CALIFORNIA ENERGY COMMISSION
HEARING ROOM A
1516 NINTH STREET
SACRAMENTO, CALIFORNIA

THURSDAY, MAY 10, 2007

9:00 A.M.

Reported by:
John Cota
Contract No. 150-04-002

PETERS SHORTHAND REPORTING CORPORATION (916) 362-2345

COMMISSIONERS PRESENT

Jackalyne Pfannenstiel, Presiding Member

Jeffrey D. Byron, Associate Member

John Geesman, Associate Member

ADVISORS PRESENT

Melissa Jones

Gabriel Taylor

Tim Tutt

STAFF and CONTRACTORS PRESENT

Linda Kelly

Rachel MacDonald

Jose Palomo

Lorraine White

ALSO PRESENT

Luther Dow, Pacific Gas & Electric (PG&E)

Bill Karambelas, FuelCell Energy (via telephone)

Russ Neal, Southern California Edison (SCE)

Tom Bialek, PhD, PE, San Diego Gas & Electric,
(SDG&E)

John Westerman, University of San Diego, Energy
Policy Initiative Center (EPIC)

Aaron Rachlin, Borderland Wind

Nora Sheriff, CAC/EPUC

M. L. Chan, PhD, KEMA, Inc.

Jane Turnbull, League of Women Voters

Steven Moss, San Francisco Community Power
Electric Co-Op

Eric Lightner, United States Department of Energy
(DOE)

Frances Cleveland, Xanthus Consulting
International

Mark McGranahan, Electric Power Research Institute

Jim Skeen

Charles Toca, on behalf of VRB Power System (via
telephone)

P R O C E E D I N G S

9:11 a.m.

PRESIDING MEMBER PFANNENSTIEL: Good morning, I think we can begin. This is a joint committee workshop of the Energy Commission's Integrated Energy Policy Report Committee and Electricity Committee.

I'm Jackie Pfannenstiel. I'm the Commission Chair and the Presiding Member of the Integrated Energy Policy Report Committee. And to my right is Commissioner Geesman who is both on that committee and on the electricity Committee. Commissioner Byron, who is the Presiding Commissioner on the Electricity Committee will join us later this morning, I believe.

This is an opportunity for us to start to develop some understanding and strategies around the effects of the distribution system, utility distribution system. Of the many changes we're making elsewhere in the electricity infrastructure. And primarily distributed generation, renewable generation.

We all know that those will have effects on the, ultimately on the distribution system. And we also know, of course, that's where the

1 connection to the customers is and that's where
2 the issues and complaints are. And that as we
3 work upstream that it will likely have some
4 effects.

5 There's been a lot of work that's gone
6 on nationally and in California on this subject
7 and we wanted to bring it into the Integrated
8 Energy Policy Report this year. So I thank
9 everybody for being here, for being willing to
10 share information and perspectives with us. By
11 the end of what promises to be a very full and
12 meaty day I think we'll all have a better
13 understanding of where we need to go with this.

14 With that, Commissioner Geesman, do you
15 have any comments?

16 Lorraine, hand it over to you.

17 MS. WHITE: Good morning. My name is
18 Lorraine White, I'm the program manager for the
19 Integrated Energy Policy Report proceeding and I
20 welcome everyone as well to this morning's and
21 today's workshop on the issues associated with
22 California's distribution infrastructure
23 challenges.

24 My job, of course, is to provide some of
25 the announcements for the day. We here at the

1 Energy Commission want to make sure that your
2 participation and your involvement in our
3 proceeding is very active. We welcome input. We
4 look very much forward to comments and questions
5 throughout the day.

6 We have here at the Energy Commission
7 some facilities that you may find useful for
8 refreshments and such. Outside the double doors
9 here we have restrooms both to the left and then
10 directly behind the elevators. We also have on
11 the second floor under the awning a little
12 refreshment/snack shop so if you need water or
13 anything like that you can get it there.

14 We have the materials for today's
15 workshop out in the foyer covering all of the
16 presentations and the agenda in more detail. We
17 also have in the event of an emergency a protocol
18 we'd like you to follow. In the event an alarm
19 sounds we ask that you exit this room calmly and
20 follow staff out the double doors here that most
21 of you entered by the security guard. Proceed
22 kitty-corner to the Commission to Roosevelt Park
23 where we will convene and wait for the high sign
24 to return.

25 For those who are here today we

1 encourage that in order for us to make sure
2 everybody is heard that if you have comments or
3 questions that you fill out blue cards that are on
4 the table in the foyer and either provide them to
5 Rachel or to Linda throughout the day so that we
6 can provide them to the Chairman and have people
7 called accordingly. We will be having an
8 opportunity related to public comment related to
9 the morning session as well as the afternoon
10 session.

11 We are also providing this workshop
12 through our webcast capabilities. Those who are
13 also going to be participating in that, or via
14 audio only, can call a toll free number. At the
15 appropriate time we'll be asking folks in the
16 call-in numbers or on the webcast if they have
17 questions so you'll be able to participate that
18 way as well. The call in number is 1-866-469-
19 3239. But information is also available on the
20 notice so you can follow the directions there.

21 We have also today the workshop being
22 covered under the WebEx capabilities. That allows
23 for much more dynamic participation as well. And
24 in the notice there is also much more detailed
25 directions on how to actually participate and hook

1 in on the WebEx.

2 Just a couple of notes about our WebEx
3 participation. We're following a particular
4 protocol to make sure that we cover everybody and
5 get the input we need. For those on the WebEx
6 please use the raised hand function. There is a
7 button there that allows you if you have questions
8 or comments throughout the course of the workshop
9 to indicate to our host your interest in making
10 those comments. She'll be able to notify the
11 Commissioners and at the appropriate time allow
12 you to ask your questions.

13 So the order of the day will be
14 questions and comments from the dais, of course.
15 Attendees that are here in person, we ask that you
16 please go to the podium there. And make sure that
17 you press the button and have the green light on.
18 Those who have raised their hand on the WebEx and
19 then the phone-in-only participants.

20 As Commissioner Pfannenstiel indicated
21 we do have a pretty meaty day and we look forward
22 to having a lot of information discussed. The
23 first part of the day will be covering the
24 distribution system in an overview.

25 We have a panel also featured in the

1 morning after presentations by the utilities to
2 provide us input on their distribution system
3 operation and challenges and then a presentation
4 on the San Diego Smart Grid Study Overview.

5 In the afternoon we'll be covering
6 issues and topics related to technology
7 innovations. We'll start off with information
8 about what our PIER program is doing, the Public
9 Interest Energy Research program, which has a
10 distribution research program. And one of the
11 topics that we're looking at there is the
12 microgrid research. We'll have a couple of
13 presentations there.

14 We also will be discussing research
15 being done on the customer end and what the US
16 Department of Energy is doing. We'll be looking
17 at system integration issues and various types of
18 emerging technologies related to the distribution
19 system itself. And in the afternoon concluding
20 most of these presentations will be the panel
21 discussion on technology. We'll conclude with our
22 public comment after that.

23 For those of you who have not yet been
24 involved in the IEPR proceeding this is a
25 legislatively mandated proceeding in which the

1 Energy Commission is to look at the energy system
2 throughout the state, electricity, natural gas,
3 petroleum, renewables, efficiency issues,
4 infrastructure issues, the lot.

5 We began the proceeding on August 1 of
6 2006 and subsequent to that we began our data
7 collection process, which will actually be
8 continued through much of the proceeding so that
9 we have a rich record on which to develop our
10 analysis and generate our results.

11 From the staff's analyses results and
12 input from various parties we'll be developing
13 various issue papers that hone in on the specific
14 topics, concerns, forecasts and analysis that the
15 proceeding requires us to generate.

16 These papers then will be the foundation
17 for us to develop policy recommendations and to
18 generate the first of the IEPR documents, which is
19 the Committee Draft of the Integrated Energy
20 Policy Report. That we'll be producing about late
21 August.

22 The Committee will hold various hearings
23 on that as they have throughout this proceeding
24 and ultimately issue a final Committee Draft in
25 late October, in time for adoption by the whole

1 Commission on October 24.

2 We're legislatively mandated to transmit
3 to the Governor and the Legislature by November
4 1st of every odd year this report and we are
5 currently quite on track to do so.

6 All of the information about the
7 proceeding is contained on our website. The site
8 pathway is listed there. And that includes
9 notices for other workshops, all of the supporting
10 documentation, information on specific issues that
11 the Committee is focused on. You can also get
12 general information from me. My contact
13 information is featured here as well as in the
14 notice.

15 And then for those who are specifically
16 interested in the work that PIER is doing, the
17 content of this workshop and any of the other
18 distribution related issues that we're working on
19 you can contact Linda Kelly. That information is
20 also in the notice.

21 With that, Commissioners, I will hand it
22 over to Linda. If anyone has any questions on the
23 process for today? All right.

24 MS. KELLY: Good morning. There was a
25 lot of good information there, Lorraine, giving a

1 lot of background on why we're here and what we're
2 doing. And so I just wanted to make one comment.

3 I think that research in any industry is
4 healthy and it helps identify issues early. I
5 think for the PIER program this is something that
6 we found. As we began doing our research
7 assessments into the issues surrounding
8 distribution I think we were able to identify a
9 range of very important issues that needed to be
10 addressed in the context of state policy. So I
11 think that PIER has served a role in identifying
12 early some of the issues that are really critical
13 to policy.

14 We have a very busy schedule today so
15 other than that comment I'm going to get right to
16 introducing everybody and getting to the
17 discussions. I'm going to start from the north of
18 the state and I'm going to go south so we'll start
19 with PG&E.

20 Luther Dow has worked with PG&E for over
21 27 years and he has worked in the public sector as
22 well. He has also worked for EPRI and he has
23 extensive experience in transmission and
24 distribution. Luther.

25 MR. DOW: Good morning. Thank you for

1 holding this workshop. As the utility
2 representatives of the PAC have discussed with
3 you, we welcome the opportunity to share what we
4 are doing and what our beliefs are on where the
5 research and challenges are. So we look forward
6 to the discussion. I'm sure it will be, it will
7 be rich.

8 So let's just start a little bit out
9 about PG&E. If I'm going to talk about the PG&E
10 experience I have to at least talk about PG&E for
11 a minute. We serve Northern and Central
12 California, have a 70,000 square mile service
13 territory, serve a population of about 15 million
14 and have 5.1 million electric customers.

15 Since the service area is so large we
16 have dense areas, urban areas, rural areas.
17 Primarily residential customers and our important
18 customers, of course, are our agricultural
19 customers.

20 I want to talk about the distribution
21 system and it is important that I go through this
22 in a little bit of detail as to one of the areas
23 of concern. To serve these five million customers
24 we have 135,000 miles of distribution line.
25 Seventy-nine percent of that is overhead.

1 We have 712 distribution stations, we
2 have almost 2400 distribution banks, 2900 circuits
3 changing daily. This time of year is when we're
4 doing all our capacity work so that number
5 probably will change twice before the day is over.

6 We have 2.3 million wood poles and we
7 have 660,000 overhead distribution transformers
8 bolted on those poles. And we have 200,000
9 underground transformers, either pad-mount or
10 completely sub-surface transformers. And we have
11 some 300,000 miscellaneous pieces of equipment
12 that also contribute, capacitors, reclosers.

13 So you can see that it takes a lot, a
14 lot of apparatus, a lot of components to make up
15 the distribution system. So it's not only that we
16 have a lot of them. I want to give you some age,
17 average age. Our substation banks, those 2400
18 substation banks, have an average age of 43 years.
19 That's the average age of those banks.

20 Our distribution breakers are an average
21 age of 26 years. Our wood poles have an average
22 age of 39 years. Our overhead distribution
23 transformers have an average age of 36 and our
24 underground transformers have an age of 18 years.
25 So you can see that not only are there a lot of

1 apparatus, there's also an aging apparatus.

2 I tried to think about how to describe
3 the R&D needs in distribution and I've summarized
4 them into three major categories. The first being
5 the component condition assessment. How do we
6 know that a piece of equipment is good or not?
7 Oftentimes unfortunately we have to wait until it
8 fails and that's not, that's not satisfactory to
9 most anyone. So when I thought about where is the
10 most important area, in my mind that is the most
11 important area for research.

12 Also, how do we integrate DER in the
13 distribution system? We are certainly supportive
14 of that. If you look at the future of the system
15 there is no doubt that DER is an integral
16 component of that. How do we do that?

17 And then of course automation,
18 distribution automation. There is a lot to be
19 learned yet about how to automate the system and
20 have it work later. So let me take a minute to
21 discuss each one of these three areas.

22 As I showed, showed you just previously,
23 there are millions of individual components. Each
24 one of those components in turn have components so
25 there are just a lot of things that can go wrong

1 in the system. And as I showed you the age of the
2 equipment is approaching the end of its useful
3 life. So we need to find a way to identify how
4 the various components are behaving and what the
5 health of those, the health of those components
6 are.

7 And I picked up two areas, sensor
8 development application. There's a lot of need to
9 -- and I think there is a lot of this sensor work
10 going on. We had our PAC meeting last week. We
11 had some staff from Berkeley there and they were
12 talking about some sensor technology that was
13 being used in the health industry.

14 And we thought well -- I was sitting
15 next to one of the professors and I said, I'm
16 trying to find a way, how can you put a sensor on
17 a wood pole so that I wouldn't have to, so that I
18 would know that that pole is going to fail. He
19 said, maybe there's something we can do, there's
20 some work that's being done elsewhere.

21 So we don't necessarily have to, we
22 don't have to develop, necessarily develop the
23 sensor but we have to be able to identify where
24 the sensor technology is and then try to find out
25 if there is a sensor there that we could use. So

1 some sensor development/application.

2 And cable diagnostics is the other area.

3 I want to talk about cable diagnostics. It
4 happens to be something that I have a personal
5 interest in. Let's talk about PG&E's underground
6 system. We have 26,000 miles of underground
7 cable. We have basically four types of cable.
8 Obviously we have a spattering of other types.
9 But if we were to take a look at our system we
10 have cross link polyethylene, ethylene
11 polypropylene rubber, high molecular weight and
12 PILC or paper insulated cable.

13 Most of our cable is cross link
14 polyethylene, 57 percent of that cable or about
15 15,000 miles. The estimated age of that cable is
16 20 years old. We have 27 percent of the system is
17 EPR so that's about 7,000 miles. And the average
18 age of that cable is five because that's the cable
19 we're using today. We started using that about
20 eight or nine years ago.

21 Then we have the older cable, older
22 extruded cable, which is the high molecular weight
23 cable. The average age of that is 35 years and we
24 have about 4,000 miles of that. And then we have
25 paper insulated lead covered cable, which is by

1 far our oldest cable. The estimated average age
2 of that is 40 years old and we have about 500
3 miles of that left in the system.

4 We have been doing some work recently to
5 replace to that cable. That right now, that has
6 been our focus on cable replacement. I expect
7 another year of that and then we will, we will
8 start to looking at other cable. So far PG&E has
9 been replacing about 70 miles of cable a year.
10 And if we have 26,000 miles of cable you can see
11 that we are at a slow replacement rate.

12 The average cost to replace cable -- and
13 this is to replace, not to install new but to
14 replace. The average cost for us is running about
15 \$120 a foot. The range is from 80 to 150
16 normally.

17 ASSOCIATE MEMBER GEESMAN: You say a
18 slow replacement rate. But if I do that
19 arithmetic that's a 371 year --

20 MR. DOW: That's the same number that
21 I've got.

22 ASSOCIATE MEMBER GEESMAN: That's not
23 really a replacement program.

24 MR. DOW: That's a slow rate. You're
25 right. But the question though is, are we

1 replacing the right cable. You know, it's not age
2 that is the issue here. It's how has the cable
3 been operated, what is the physical environment in
4 which the cable has lived its life. Has it lived
5 in a very dry area, has it lived in a wet area.
6 Has it had a lot of -- Is it an area where there's
7 a lot of faults or is it an area that has been
8 loaded, has been very lightly loaded.

9 So you have to -- The cable age depends
10 upon how the cable has been treated. It's just
11 like a human being. It's just like us. How have
12 we treated our bodies and how we have lived our
13 life. Now there's also some inherent problems.
14 The type of cable also has some inherent problems
15 just like our bodies have some inherent defects.

16 I want to make sure, I think if you
17 press those numbers out, 70 miles at \$120 a foot,
18 that's about \$45 million. I expect that that will
19 increase substantially in the next few years. And
20 we're okay with doing that provided that we're
21 replacing the right cable. How do we know that
22 we're doing the right work at the right place? We
23 spend the money here and we have failures over
24 here. Is that a good use of our work?

25 So there are two needs. There are two

1 needs that I see. And one of them is to be able
2 to determine the health of the cable. And there
3 has been a lot of work done on that across the
4 nation. A lot of evaluating different types of
5 tests and trying to determine how we can determine
6 the health of the cable.

7 And in fact I think most of us when we
8 look at trying to determine the health of the
9 cable we do look at what type of testing can we
10 do. What test is it that will tell us.

11 Well, in part of the PIER work we were
12 looking at this slightly differently. We were
13 looking at this saying, what type of sensor can we
14 install that could give us some attribute or some
15 attribute of the cable that we might be able to
16 use. So rather than having to go out and do some
17 testing maybe there are some sensors that we can
18 install that will provide us some information.
19 It's different from how I've been used to seeing
20 that and I look forward to the way we're going to,
21 we're going to proceed down that path.

22 Then once we've determined the health of
23 the cable then how can we predict the remaining
24 life. I think a lot of times when we do this work
25 there's an inclination to say, well let's develop

1 a new cable. We've learned all this stuff, how
2 can we build a better, a better cable. That's
3 nice and I think as long as it's, as long as it's
4 an additional outcome that's fine. But the
5 purpose here is not to develop a better cable, the
6 purpose here is to determine how can we make sure
7 we understand how our existing cables work and
8 what we can do about them.

9 The next area that I believe we need to
10 do some work in is how do we integrate distributed
11 resources into the distribution system. There is
12 no doubt that the distribution system of the
13 future, DER is going to be an integral part of
14 that system.

15 The distribution system of the future is
16 going to be a partnership between the utility and
17 the customer and it is going to be used by both
18 the utility and the customer. It is going to be
19 used by the utility to provide service and it's
20 going to be used by the customer to provide energy
21 into the grid or to customers or others. So we're
22 both going to be using that system.

23 How do we do that? What are the -- How
24 does that work? What does it mean when every home
25 has a solar panel on it? What does it mean when

1 every home has a solar panel on it and the
2 inverter doesn't work? What does it mean when you
3 have an outage and the person who has DER
4 connected to his or her home wants to serve his
5 neighbor or his neighbor wants to be served by
6 him? That would make sense to do that.

7 So we really do need to understand the
8 impact on the distribution system of further
9 acceptance by the marketplace of DER. And there
10 are adaptive protective devices that are
11 necessary. As the load shifts we need to make
12 sure the system is protected.

13 Microgrids. I'm convinced that
14 microgrids are going to be a part of the
15 distribution system. How do they work? How are
16 you going to do that? How are you going to have a
17 system that automatically separates from the
18 system, serves a load and then when the system is
19 restored can go back? There's a lot of technology
20 there that has to be done to make that happen.
21 But we need to do that because that's how we're
22 going to, that's how we're going to allow the
23 customers to fully utilize the DER that they're
24 installing on their, on their facilities.

25 And the last piece is storage

1 capability. In my mind you have to be able to
2 store energy and we need to have a way of having
3 batteries or other storage devices that are
4 connected to the distribution system. How does
5 that work, how do we do that? So DER is an
6 important piece.

7 Now the last area that I think is
8 important is distribution automation. A lot of
9 people talk about distribution automation and they
10 say they have SCADA. SCADA is a subset in my
11 mind. SCADA is a subset of automation.

12 If we want to improve the reliability, a
13 step function, if we really want to say, if we
14 want to go from here to here in my mind the way to
15 do that is to automate the system. We can replace
16 every component that's bad and we can continue to
17 -- because every component contributes a little
18 bit to the reliability of the system. So if we
19 replace all of the cable we will incrementally
20 increase the reliability of the system. If we
21 automate the system, in my mind, we will, we will
22 make a step function in that process.

23 PG&E uses, PG&E uses SCADA, mostly in
24 substations, some field. We have developed, just
25 completed a distribution automation roadmap that

1 has provided us a long-term view of where, how we
2 can implement the distribution automation into the
3 PG&E system. That roadmap is --

4 ASSOCIATE MEMBER GEESMAN: Is that a
5 public document?

6 MR. DOW: No, that process, that is just
7 now going through the approval process.

8 ASSOCIATE MEMBER GEESMAN: When it is
9 approved will it be something that we could get
10 access to?

11 MR. DOW: I'm sure you could. But it's
12 not, it has not been, it has not been approved
13 through the process.

14 ASSOCIATE MEMBER GEESMAN: Sure.

15 MR. DOW: But we're there and we intend
16 to do some automation somewhere in the system this
17 year based on that roadmap.

18 So what are the needs there? Open
19 protocols. We've all heard about the need for
20 open protocols and operability with existing
21 systems. All of the problems that pertain and
22 there's a lot of work being done in lots of places
23 about that. Lots of good work being done in lots
24 of places about that.

25 Sensor technologies. Just like before,

1 when you have distribution automation you have the
2 ability to have, to gather information about the
3 health of your system. And we need to have
4 sensors that help us do that.

5 Power electronics for rapid fault
6 clearing and other types of operations in the
7 system. We have a, we have a, we have a 21st
8 century load and a 20th century distribution
9 system. We have mechanical devices operating,
10 spending time operating breakers and we have
11 customers who don't want to see any interruptions.
12 So we have power electronics to help us in that
13 process.

14 ASSOCIATE MEMBER GEESMAN: You have a
15 mid-20th century distribution system.

16 MR. DOW: We have a mid-20th century,
17 thank you for the correction.

18 And again, we need adaptive protective
19 relaying and we need to be able to anticipate the
20 fault. There's a lot of nice work being done in
21 EPRI and other places about trying to anticipate
22 where faults may occur and being able to provide
23 that information. If we can do that then we can
24 provide that, we can sectionalize that piece of
25 line. Automatically we can reconfigure the system

1 and not involve an outage to customers.

2 PRESIDING MEMBER PFANNENSTIEL: Luther,
3 how do you see the AMI, the advanced metering
4 infrastructure that PG&E is moving rapidly
5 towards, to affect this?

6 MR. DOW: I think AMI is going to
7 provide, will be an input into the system. It
8 will be able to take that AMI data and then be
9 able to operate the system based on that AMI, that
10 AMI input.

11 PRESIDING MEMBER PFANNENSTIEL: Will it
12 change some of your thinking on the R&D needs?

13 MR. DOW: No, no.

14 PRESIDING MEMBER PFANNENSTIEL: These
15 are then given AMI. This is what you still need.

16 MR. DOW: Yes.

17 Let me summarize and close this piece
18 about -- I spent some time with EPRI doing
19 research and I want to close with these thoughts
20 about, about how I see research. There's a lot
21 that can be done. Everybody has an idea and
22 everybody has a good idea so there's just a lot of
23 areas.

24 So you need to, you need to really focus
25 on what's important. You need to get down and

1 say, what are the, what are the things that are
2 really, will really impact you, us or whoever is
3 doing the decision-making. What will impact us.
4 And focus on what's really important there.

5 Because it's really easy to step aside
6 and say, isn't this cute. This is a really nice
7 idea, it's really easy, I can do it very quickly,
8 but now you've lost your focus on what is really
9 important. So we really need to, we really need
10 to stay on track with what's important.

11 And we need to -- There's not a lot of
12 research dollars out there so we want to make sure
13 that we don't duplicate that. We need to partner
14 with others. The one thing that I really like in
15 the PIER process is that they are partnering with
16 other organizations, pulling together and joining
17 and saying, they're doing that work, let us
18 support them, let's join in with them, and I think
19 that's a really important way to do that.

20 We need to continue regulatory support.
21 We need to be rewarded for innovation and not
22 penalized when some of this research material
23 fails. Because research is that. Some of it is
24 going to work and some of it is not. So we need
25 the support of the regulators to be able to go

1 forward and do, to be innovative.

2 We need the involvement of all
3 stakeholders. That's another nice thing about the
4 PIER process is that all of the utilities are here
5 and we invite stakeholders and the stakeholders
6 have a chance to speak. And that's, that's an
7 important thing.

8 And finally, research is not necessarily
9 a product. Research is knowledge. Research is
10 learning how things work so then you can take the
11 next step. And I have seen research programs fail
12 because they promised a product. And they
13 couldn't deliver on the product but they had
14 really good information that could be used for
15 other things.

16 And so we need to recognize that when we
17 do this research it doesn't mean at the end of the
18 day we now have, that we now have a device. But
19 rather we have some additional knowledge on which
20 we can build and then take the next steps.

21 And so I think that's the end of my
22 presentation and -- Are we going to do questions
23 later?

24 ASSOCIATE MEMBER GEESMAN: Luther, I
25 wanted to ask you whether there are commonly

1 accepted quality of service metrics applied to the
2 distribution system, either internal to PG&E or
3 within the industry overall?

4 MR. DOW: In PG&E we are looking,
5 relooking at our reliability metrics. I think
6 reliability metrics in general in the industry
7 have been focused on the utility and not focused
8 on the customer.

9 And we are, we are doing right now
10 looking at various ways. And I'm sure that the
11 metrics we have now are going to be different from
12 the metrics we have next year. But I would say
13 they are probably not.

14 There are some accepted ones but I don't
15 think they're the right ones. If you really want
16 to say, our job is to provide the best darned
17 service we can to the customer, then those metrics
18 are not good.

19 ASSOCIATE MEMBER GEESMAN: With the
20 legacy system that you now have what's the trend
21 line in terms of the quality of service metrics
22 that you have been applying?

23 MR. DOW: The typical SAIDI and SAIFI,
24 they have been declining.

25 ASSOCIATE MEMBER GEESMAN: And I would

1 presume with the aging nature of the
2 infrastructure your projections are that that
3 decline will either continue or accelerate.

4 MR. DOW: Unless we do something about
5 it, and we are doing things about it. We're doing
6 a lot to stop that decline. But you're right, if
7 nothing happens, with status quo it will continue
8 to get worse.

9 ASSOCIATE MEMBER GEESMAN: Thanks very
10 much.

11 PRESIDING MEMBER PFANNENSTIEL: Two
12 questions. First, is PG&E doing any of its own
13 research in the distribution area or is it doing
14 it through EPRI and working with PIER?

15 MR. DOW: It's not doing a lot. A
16 little bit of definition of what is research, I
17 suspect, but most of it is done through EPRI and
18 through PIER. We are doing a few small products
19 and trials but there's not a large research
20 program.

21 PRESIDING MEMBER PFANNENSTIEL: And then
22 the other question. You said at the outset that
23 79 percent of your system is overhead. Is that a
24 fairly static number? Are you moving more towards
25 underground, are you staying with overhead? I

1 know the cost difference is enormous.

2 MR. DOW: Yes.

3 PRESIDING MEMBER PFANNENSTIEL: But how
4 does the system seem to be going?

5 MR. DOW: Well the percentage is getting
6 more underground, primarily because all the new
7 development is underground. So the percentage of
8 underground is getting larger.

9 PRESIDING MEMBER PFANNENSTIEL: And
10 that's for new development. Are you seeing much
11 in the way of undergrounding existing systems?

12 MR. DOW: Mostly through the Rule 20
13 process, the Rule 20A, 20B, 20C.

14 PRESIDING MEMBER PFANNENSTIEL: But is
15 that significant? Does that really make any
16 difference?

17 MR. DOW: It's a relatively small
18 amount.

19 PRESIDING MEMBER PFANNENSTIEL: Thanks.

20 MR. DOW: Any other questions?

21 MS. WHITE: Just as a clarification,
22 everybody knows that if you want to ask a question
23 you fill out a blue card. We have no blue cards.
24 We have nobody on-line. Is anybody -- Does
25 anybody on the phone have a question? Hearing

1 none I thank you very much, Luther.

2 MR. KARAMBELAS: Yes, actually I do.

3 MS. WHITE: Go ahead. Can you state
4 your name.

5 MR. KARAMBELAS: My only question is --
6 Bill Karambelas, FuelCell Energy. I would just
7 like to request if I could get the contact
8 information for the presenter back up on the
9 webcast so I can write down the information.

10 MS. WHITE: Okay.

11 MR. KARAMBELAS: Thank you.

12 MS. WHITE: All right. Just contact me
13 and I'll make sure that you get this information.

14 Just as a point of clarification, I
15 think as each of the utilities come up and make
16 their presentation each of these presentations is
17 very unique to the utility so I thought we would
18 do questions in-between these presentations. And
19 then during the panel discussion we can have
20 broader, more general discussions at that time.
21 But I did want to, as long as it wasn't too long,
22 have questions in-between the individual
23 utilities. So we'll proceed in that way.

24 Again, if you have questions please fill
25 out the blue card and give them to Rachel right

1 here or myself and then we'll pass them on to the
2 Chairman. Okay?

3 All right, the next person is, moving
4 down the state is Russ Neal. Russ Neal is the
5 manager of distribution system planning for
6 Southern California Edison. He is responsible for
7 assessing load growth and sponsoring both load
8 related expansion projects and infrastructure
9 replacement projects for the distribution system,
10 Russ.

11 MR. NEAL: Thank you Linda,
12 Commissioners. This is going to be just a short
13 presentation on the distribution system and some
14 of its operations and challenges from our
15 perspective here at SCE.

16 I would like to echo Luther's comments.
17 We appreciate this opportunity to be able to make
18 a pitch for the distribution part of the system
19 which is sometimes seems like it's the bottom
20 floor of the building is some ways and may not get
21 as much visibility but it's pretty important for
22 the upper two stories.

23 The distribution system, of course, is
24 important because it represents the larger part of
25 the T&D system. It represents 80 percent of the

1 dollars that are sunk in the ground and steel,
2 concrete, aluminum and copper.

3 We've gotten quite a bit of exposure to
4 the fact that we have a very aggressive
5 transmission building program in the next few
6 years but out of our total ten billion dollar
7 capital investment, capital budget over the next
8 five years, 70 percent of that will still be in
9 the distribution area. So it is still the whale
10 in the bathtub financially speaking.

11 And of course the distribution failures
12 account for 90 percent of customer reliability
13 problems. That's the transmission system
14 obviously networked and having some more
15 redundancy in it. Individual failures there do
16 not as often cause customer outages. But with the
17 distribution system being basically radial,
18 individual failures there do cause interruptions
19 of service to the customer.

20 And of course we add a note here that
21 the, there's reliance being placed on the
22 distribution system and a lot of thinking going
23 forward to be able to roll out, distributed energy
24 resource solutions for some of our problems so
25 that, that's an additional reliant which is being

1 placed on that system.

2 From SCE's point of view, what are our
3 priorities? What do we see as our big challenges.
4 The priority and challenge that we've been
5 experiencing most recently has just been to meet
6 the load growth that we've been experiencing.

7 In the last few years we've had
8 unexpectedly high growth rates that we've had to
9 meet. And in our particular case it's
10 significantly exceeded our projected load growth
11 which was the basis of our rate case and our rates
12 and put a great deal of pressure on the company to
13 be able to meet that to some extent at the
14 expense of the next bullet of maintaining
15 reliability.

16 The issue here is that similar to what
17 Luther was talking about of replacing this aging
18 infrastructure. And some of our planned efforts
19 in that area suffered as a result of the need to
20 divert some resources to meet the unforecast load
21 growth.

22 So we're quite concerned about this area
23 of how we're going to be able to maintain that
24 reliability going forward and of course the
25 distribution cables are probably the single

1 biggest component of our system of concern.

2 There's one extra item that I did want
3 to touch on here today which is this subject of
4 air-conditioner stalling which is kind of
5 something we're beginning to identify now as a
6 threat to both the power quality and potentially
7 to the reliability of the overall system. And
8 I'll be speaking about that in a few moments here.

9 And then finally, we understand that
10 being pressed on all sides the one hopeful thing
11 that we do have is emerging technology may enable
12 us to be able to get through some of these thing.
13 So we wish to be able to explore the technological
14 avenue of solving some of these problems more
15 aggressively.

16 I'm going to be sharing a little bit
17 here on one thing that we're doing at the
18 distribution level there that which call our
19 Avanti circuit. Or sometimes we call it our
20 circuit of the future.

21 Where we've simply taken one of our
22 distribution circuits that we're building out of
23 the many we build every year and we've set it
24 aside as sort of a technological showcase or a
25 vehicle on which emerging technology can be tried

1 out.

2 And so different types of technology can
3 be, have integration efforts worked out that
4 particular circuit.

5 On the subject of cable this particular
6 histogram shows how many conductor miles of the
7 various types of cable that we've installed
8 similar to, somewhat similar to the ones that PG&E
9 has. There's one difference to it.

10 We start with the paper insulated lead
11 covered cable right here which was the historic
12 type of cable. We had a little experience with
13 the high molecular weight which was not very
14 favorable. So we got away from that and settled
15 in on cross-linked polyethylene cable which is the
16 bulk of our installation.

17 Our installation is a little bit
18 different than many others. We have a lot of
19 this. Almost all of this isunjacketed. And
20 almost all of it is either in conduit or in what's
21 called CIC or conduit in cable which is like a
22 softer conduit that's laid in the trench at the
23 same time as the cable.

24 That's not as common, that's not the
25 most common way it's done in the industry.

1 And we've migrated recently to an
2 upgraded cable which is called tre-retardant
3 cross-linked polyethylene as opposed to the EPR
4 that some other utilities have gone to.

5 We also have decided to go with putting
6 jackets on it at this time and doing some other
7 upgrades to the cable based on the fact that the
8 people right here are having to live with the
9 decisions made right here, right now. So we're
10 trying to do a little bit better for our
11 descendants.

12 ASSOCIATE MEMBER GEESMAN: What does the
13 jacket do for you?

14 MR. NEAL: The jacket provides physical
15 protection to the working parts of the cable. The
16 cable itself, you have the central conductor, then
17 you have an insulating material. And then there
18 is like a, on top of that is what's called a
19 shield type of material.

20 And that physically consists of a semi-
21 conduction poly black plastic, polyethylene that's
22 extruded in a thin layer on top of it. And then
23 you'll sometimes see a, you'll always see in our
24 case copper wires wound in a spiral around that.

25 That produces a ground plane around the

1 insulation so that the real insulation, the cross-
2 linked polyethylene will feel a geometrically even
3 distribution of voltage stress on it so you don't
4 have stress concentrations at different points
5 which lead to the failure.

6 During installation of these cables it's
7 possible for that jacket to get slightly damaged.
8 It's during the service life that that concentric
9 neutral copper wire is subject to corrosion. And
10 the jacket reduces both of those two effects which
11 can be contributors to cable failure.

12 In particular when that concentric wire
13 deteriorates it's used to carry some of the ground
14 return current back to the substation if you want
15 to think of it that way. And when that is
16 deteriorated some of that return current finds its
17 way back to the substation through the earth.

18 And that sometimes results in the
19 complaints that you hear about stray voltage. And
20 sometimes has an effect especially on like dairy
21 production. And it can also result in people
22 experiencing some shock potential sometimes. In
23 particular if the plumbing in the house is
24 different than the doorknob in the house and
25 sometimes you can have some electric shock hazards

1 from that.

2 We also, I'm also of the belief although
3 we haven't proved it, but that also contributes to
4 the subsequent deterioration of the cable because
5 of the current trying to get past these areas of
6 failed concentric wire.

7 This particular graph shows our
8 calculated, our assessed prediction of cable
9 unreliability it's called. In other words, when
10 will it fail? Down in these years it won't fail.
11 It's got like a zero chance of failing. And out
12 here it's a 100 percent chance of failing.

13 And this shows the four types of cable
14 that we were talking about. And of course the
15 cross-linked poly being the major one here, about
16 a 50 percent failure probability is somewhere in
17 the 35 year time frame.

18 We took those two pieces of information,
19 the histogram that says what's out there and how
20 old it is and we took those failure prediction
21 curves and we have done a study that says what
22 will be the projected impact on our principal
23 measures of reliability, the SAIDI and the SAIFI.

24 So this other curve shows what we
25 project for the SAIDI or the duration issues.

1 Right here we're at 2007 we're experiencing a
2 number like 60, 63 minutes as an average number of
3 minutes customers experience their outages.

4 We show a number of the factors that
5 contribute here, storms and so forth as being flat
6 lined. Some of the equipment reliability issues
7 will be getting worse in the future no matter how
8 well we do even in a fairly optimistic case of
9 replacing equipment.

10 And then these top curves here from the
11 purple one and the green one represent various
12 cases of cable replacement programs.

13 So if you do no cable replacement and
14 allow it to run to failure you'll be running on
15 that top curve, the top of the purple. And then
16 various things running from a 100 mile per year up
17 to a 600 per mile year of cable replacement are
18 shown down here.

19 In the worst case you would basically in
20 the next 20 years you would double the SAIDI
21 numbers that the customers are experiencing if we
22 do nothing. We're not doing nothing right now.
23 But that's probably the curve we're the closest
24 to.

25 And this is the same thing for the SAIFI

1 or the frequency at which people are experiencing
2 these interruptions. And in that case it's
3 similar but in 20 years people will be
4 experiencing about 50 percent more than they do
5 today if we don't do anything.

6 Even if we have a very aggressive 600
7 mile a year rate which is more than 10 times
8 anything we've ever done, if we had that and
9 sustained that for this next 20, 30 years you're
10 still seeing the situation get worse every year
11 even under a highly optimistic situation like
12 that.

13 The subject of air conditioner stalling
14 is something we've observed, It turns out that
15 small capacity, less than 15 ton air conditioner
16 compressors, stall on momentary voltage dips.

17 Actually they all stall, but the larger
18 ones are always equipped with an under-voltage
19 trip device that removes them from the system when
20 that happens.

21 The reason they stall is because once
22 they're running that compressor has pressurized
23 gas in it. The motor no longer has the ability
24 once it stops to restart in that condition. It
25 has to wait for that to bleed off before it's able

1 to restart.

2 Because what happens to the smaller ones
3 is they'll stay connected to the system trying to
4 turn, unable to turn, and what removes them is
5 their thermal overloads over a certain number of
6 seconds or minutes, well seconds really that they
7 actually remove.

8 They then reset themselves. The
9 customer never knows it happened. But the system
10 might know that this had happened if it's a large
11 percentage of the connected load at that time.

12 It can cause a slow voltage recovery.
13 And in the extreme case it could even threaten
14 system voltage collapse. I mean potentially
15 throughout the entire connected western grid.
16 But that would be an extreme case of it.

17 We're actually, one of the issues is in
18 attempting to model that we're very uncomfortable
19 with our models. The PIER program, the
20 transmission road is doing a lot of work in that
21 area to try to improve our modelling capabilities
22 so that we have a better idea of what we're
23 dealing with here.

24 An ultimate solution to this would be to
25 actually install under-voltage trip devices on

1 these smaller air conditioners the same way it is
2 on bigger air conditioners.

3 An alternative to trying to fix it at
4 the utility system level appears to be technically
5 not feasible. One of the questions we're
6 wrestling with right now and we've been having
7 some discussions with Commissioner Rosenfeld
8 especially about this issue and we went back and
9 talked to FERC Commissioner Wellinghoff also about
10 this.

11 Is what regulatory or legislative venue
12 would be the right way to go forward with trying
13 to get something like this included in residential
14 air conditioners. That's one place we're at right
15 now.

16 This shows what I'm talking about. This
17 represents the voltage that you're experiencing on
18 a distribution circuit someplace. And let's say
19 at the transmission or sub-transmission level
20 there's a momentary fault what would normally
21 occur is that fault would drag the voltage down
22 very low but then within like a tenth of a second
23 or so that would be cleared by the transmission
24 breakers and voltage would pop back up to one and
25 this would just be a down glitch that people would

1 barely feel.

2 But because air conditioners stall
3 during this time if you have a large number of
4 them stall on the connected circuit the voltage
5 will not fully recover until those thermal
6 overloads remove it over a period of time.

7 This shows a period of about 20 seconds
8 here to get back during which time the system was
9 trying to correct that voltage so there's an
10 overshoot due to load tap changers, capacitors,
11 that sort of thing. And there can be
12 complications down stream.

13 And an extreme case of this could lead
14 to a voltage collapse. That's what we're looking
15 at.

16 ASSOCIATE MEMBER GEESMAN: Have you
17 always experienced this phenomenon in the air
18 conditioning portions of your service territory?

19 MR. NEAL: The first recorded, the first
20 thing I've been able to find in writing on this
21 was a case, and I believe it was Tennessee in '86.
22 And there's a paper on that. The first time it
23 came to our consciousness we had an event '96 when
24 an airplane hit a 500 kV line.

25 And we had this situation over a wide

1 area of our system for more than 30 seconds, very
2 noticeable to our operators who were just biting
3 their fingernails of watching this voltage try to
4 crawl back up.

5 By the time we did recover we had lost
6 3,000 megawatts of load. So it was a huge event
7 to us. And it got us worried about this.

8 But then we started looking at it much,
9 much more closely and started seeing it all the
10 time. But most of them would be like five second
11 delay that's from 95 percent and you wouldn't have
12 ever noticed it if you weren't looking for it.

13 So we've been aware of this for some
14 time. We observed in the summer of 2005 about
15 three events that came to our attention. This is
16 one of them.

17 And then last summer we recorded 30 of
18 them. I'm not sure how much of that represents
19 the increase in incidence and how much of that
20 represents the fact that we were looking a lot
21 harder.

22 But I do know that we have been
23 experiencing a lot of this residential
24 construction on circuits where a lot of the load
25 is air conditioning out in hotter areas. And so

1 there, that sort of thing is happening.

2 Like I said, most of these occur when
3 you're having, we don't have a whole lot of 500 kV
4 faults occur at just the right time. And because
5 our models are so-so we really aren't really
6 completely certain how much risk is involved with
7 this under a worst-case scenario.

8 ADVISOR TUTT: I take it that this has
9 nothing to do with the type or vintage of air
10 conditioner?

11 MR. NEAL: It has a little bit to do
12 with it. The newer high efficiency are a little
13 bit more subject to this. But they're all subject
14 to it.

15 PRESIDING MEMBER PFANNENSTIEL: And
16 explain what is the technological fix. You said
17 that you know how to fix it.

18 MR. NEAL: Yes, at the air conditioner
19 you would have to have a sensor which is observing
20 the voltage dip. And if it dips below a certain
21 threshold for a certain amount of time it would
22 disconnect the compressor from the system at that
23 time. It would not wait for it to heat up and
24 disconnect over many seconds. It could remove it
25 in less than a second, right away.

1 But that has to be at the air
2 conditioner to do it. The alternative of dropping
3 entire circuits is not much of a solution.

4 I mentioned that in the technology area
5 we have what we call our circuit of the future,
6 the Avanti Circuit. And as I've said I've
7 described this a lot of times to people as a
8 Christmas tree on which you can put ornaments.

9 It's a regular distribution circuit
10 coming out of one of our substations in the city
11 of San Bernardino. It should be in service in
12 July of this year.

13 And it is being built to have the
14 capacity to accept various types of emerging
15 technology to allow us to test it out.

16 So for example, we're installing a
17 fiber-optic duct temperature monitoring system.
18 We have a cement pad here with a by-pass switch
19 that will accommodate a fault current limiter that
20 the Energy Commission is working with EPRI to
21 develop.

22 And there are several other developers
23 that we're working with. And so the circuit is
24 built such that you can put one in, try it out for
25 a period of time, swap it out without interrupting

1 anybody's load. There's that type of a thing.

2 We have a facility to allow connecting
3 various types of stored energy or distributed
4 generation to the circuit with communication back
5 into the substation and SCADA system to try out
6 different paradigms in which the DG is not merely
7 riding on our system but is actually can be
8 treated as a system asset in some way, through
9 some type of control paradigm that is yet to be
10 worked out.

11 Places where today we just have ordinary
12 switches out there we're putting in vacuum fault
13 interrupters. Normally you couldn't put many of
14 them in line with each other because you couldn't
15 coordinate them.

16 You wouldn't get the advantage of only
17 the downstream one tripping. They would all trip.
18 But what we're doing is stringing fiber optic
19 between them allowing them to communicate and
20 thereby achieve coordination where with old
21 technology you couldn't do that.

22 We have some things shown on here that
23 we're not really doing yet but there just a
24 twinkle in my eye. Like some little spot
25 secondary networks in a customer so a customer

1 would receive no interruption every time a primary
2 circuit interrupts. Most customers would not
3 experience an interruption.

4 We're looking at something better than
5 just capacitor banks for the reactive power
6 support. Right now we're looking at a type of a
7 distribution level, what they call a static VAR
8 compensator which is a bunch of capacitors
9 switched in and out by solid state so that you can
10 ramp in and out the capacitance.

11 One thought is, you mentioned the issue
12 of power quality concerns that customers are
13 having. A fault on another circuit over here is
14 felt by all of these poor guys over here.

15 If you just put some simple impedance in
16 the area here like a reactor, a coil of wire, and
17 if this was a fast reacting static var compensator
18 it might be able to buffer this circuit so that it
19 would not see the voltage dip so bad. So maybe if
20 before it would have seen a 20 percent voltage dip
21 now it will only see ten.

22 And that might make all the difference
23 to some customers who have ride through issues
24 with sensitive equipment.

25 And then we show that perhaps some early

1 deployment of AMI and how that might coordinate.
2 How distribution transformers might be able to
3 phone home to our system through this
4 communication links.

5 There's a lot of things that we are
6 doing here. And the way we're approaching this
7 particular circuit is we're providing the
8 Christmas trees. We're looking for other people
9 to provide the ornaments. We're trying to partner
10 with vendors, with resource organizations, with
11 DOA, with CEC, with whoever and provide a platform
12 for these type of collaborative efforts.

13 And so in conclusion I just would point
14 out that the distribution system represents the
15 largest part perhaps of the, at least of the T&D
16 system, maybe the whole power system.

17 Its performance primarily defines system
18 reliability from the point of view of the
19 customer. And that public policy needs to
20 recognize its importance by supporting cost
21 recovery for planned investments and perhaps
22 helping us with these air conditioning codes and
23 standards issue.

24 I'd like to just also touch on the one
25 issue that you brought up with Luther there which

1 is the research funding. of course the way that
2 utilities make money is we just get a certain
3 percent of return on our capital investment.

4 And R&D is of course an O&M expense. So
5 effectively it's money just taken right away from
6 the shareholder in exchange for which they have no
7 opportunity to make any profits. So there is a
8 lot of dis-incentive there.

9 In our current rate case before the
10 Public Utilities Commission we're going to be
11 asking for some additional funding there.

12 The funding we do through PIER I think
13 is very good. I think all of us have really
14 benefitted if nothing else from the fact that you
15 got us all together. So that Luther and Tom and
16 myself can sit around a table and discuss what
17 we're doing. And there are some efforts that
18 we've initiated that really, none of us as an
19 individual utility would have undertaken. And so
20 as a collaborative it's good but the flip side is
21 that when utilities have their own funding and
22 their own manager and their own research, they can
23 move a lot faster on a lot of other little
24 projects that might have some pretty good quick
25 pay off.

1 So that's the conclusion of my
2 presentation and I'm happy to take any questions.

3 ASSOCIATE MEMBER GEESMAN: Russ I want
4 to thank you for your presentation and also to
5 just reiterate to you that the Avanti Circuit is a
6 very high priority PIER project and something that
7 we've benefitted from in its early stages and hope
8 to see blossom quite a bit more in the future.

9 Commissioner Rosenfeld and I on the R&D
10 Committee have previously tried with not much
11 success to encourage our colleagues at the PUC to
12 support the transmission R&D activities of your
13 company.

14 I think that the same applies in spades
15 with respect to the distribution efforts. And
16 we're happy to extend that as yet unproven offer
17 of assistance if you feel it can be of benefit.

18 I do think that given the
19 reliability projections that you and other
20 companies in the industry are making in terms of
21 future from a customer perspective really
22 underline the need to do a lot more in this area.

23 And I'm confident that over time our
24 colleagues at the CPUC will recognize that as
25 well.

1 PRESIDING MEMBER PFANNENSTIEL: Any
2 other questions?

3 MR. NEAL: Are there any other questions
4 Commissioner?

5 MS. KELLY: Any blue cards, are there
6 any blue cards.

7 Unidentified audience member: I have
8 one but we'll be back in the pm.

9 MS. KELLY: Oh, okay, fine. Any
10 questions on the telephone?

11 UNIDENTIFIED TELEPHONE SPEAKER: No
12 we're okay.

13 MS. KELLY: Okay, thank you very much.
14 Thank you Russ.

15 MR. NEAL: If you'd indulge me for just
16 one more comment I would like to be able to make.
17 The state is moving down the road now to make some
18 very significant investments in the area of
19 generation and transmission.

20 And we just don't want to be the last
21 one to the trough to get funded for some of these
22 distribution issues (laughter), thank you.

23 MS. KELLY: Thank you Russ.

24 ASSOCIATE MEMBER GEESMAN: Well I guess
25 I can add to that. Your trough is proportionately

1 larger than any other aspect of the capital budget
2 within the industry in California and elsewhere.

3 And it's incumbent upon government to
4 make certain, we're putting a high quality of
5 pretty modern feed into the trough. It doesn't
6 make a lot of sense to simply rely on 1957 Chevy
7 technology. It was a great car. But it's not
8 particularly well designed to the needs that we
9 face in the future.

10 MS. KELLY: Thanks Russ. The next
11 presenter moving all the way down the state, we're
12 now down in San Diego. Tom Bialek has more than
13 22 years experience in the design, development,
14 evaluation and applications and testing of
15 electric power equipment and the electric grid.

16 His present responsibilities include
17 technical oversight role on transmission and
18 distribution issues including equipment,
19 operations, planning, distributed generation and
20 development of new technologies, Tom.

21 DR. BIALEK: Thank you Linda. Thank you
22 Commissioners for having us here today. Again I'd
23 like to also reiterate that we the IOUs in
24 California really do appreciate the opportunity to
25 come here and talk about distribution issues.

1 I think that you will see from my
2 presentation, you're going to hear a lot of the
3 same kinds of things that you heard from both
4 Luther and Russ.

5 Particularly in regards to what the
6 distribution system is, what it does. I went off
7 here earlier sort of draft that Linda had as far
8 as sort of an outline. And so I will probably
9 talk about a little bit different subjects than
10 perhaps Luther and Russ had talked about.

11 So here's an overview of my
12 presentations. What I would really like to first
13 touch on is what, issues in regards to the
14 distribution system.

15 Really the aging infrastructure and
16 maturing workforce. Not only do we have a aging
17 infrastructure simultaneously we have a maturing
18 workforce as well.

19 Utilization of distribution automation,
20 what that means both SDG&E as well as beyond,
21 further applications.

22 Talk a little bit about communication
23 control technologies. You may think that we're an
24 electric power utility but in some respects we
25 also got a very large communication and sort of

1 communication technology infrastructure as well.

2 Integration of DER by SDG&E and end
3 users. A little bit about the San Diego Smart
4 Grid Study because we are one of the co-funders of
5 that particular study.

6 I would like to talk about service
7 reliability levels.

8 And then lastly from our perspective and
9 a concluding perspective, talk about what we see
10 as from an SDG&E perspective, public policy
11 support needs.

12 So I'm not going to go into a lot of
13 detail. You've heard a lot about how we've got
14 transmission, you've got distribution systems.
15 You can see here our statistics. One of the
16 things here to point out is that based upon our
17 FERC FPR, 1 filing ratio the installed
18 distribution and transmission plan equals 3.2.

19 We've got a lot of miles we're the
20 smaller utility IOU in California. But you can
21 see the same kinds of issues.

22 What I would like to spend some time
23 with here and here is some graphs and a little bit
24 of a different presentation versus what you saw
25 from both Russ and Luther.

1 What you've got in these cases are
2 distribution 12 kV banks and here is our poles.
3 And all I've plotted here is the cumulative
4 percentage in this case of banks and in this case
5 of poles versus age. And really the point to take
6 away from this is that, you know, realistically
7 the infrastructure is aging. And it's aging
8 fairly significantly.

9 In our particular case 32 percent of our
10 12 kV banks exceed 40 years of age. And 49
11 percent of our poles exceed 40 years.

12 Now moving on to what is usually the
13 favorite subject, cables. Same kind of issue with
14 cables.

15 What's plotted over here is actually our
16 predictions of actual cable failures with 90
17 percent confidence bounds as well as the actual
18 failures that are in there.

19 So what you see is that again in this
20 case 18 percent of our cables are at least 30
21 years old. We're seeing increasing failure rates
22 versus time.

23 But what we're seeing is particular
24 vintages of cable are really the drivers behind
25 this upturn in cable failures.

1 Clearly the replacement costs of all the
2 banks, poles and cables that we have today is huge
3 for us. Something on the order of 4.8 billion
4 dollar investment just in those particular areas.

5 And if you just took an age perspective
6 on all of this and said I'm going to cut at 40
7 years for banks and poles and 30 years for cables,
8 you're talking on the order of an investment of
9 about 1.8 billion dollars.

10 So clearly we at SDG&E believe that we
11 think that better tools, technology and systems
12 can help optimize our system replacement.

13 We have built into our reliability
14 analysis some predictive reliability assessment
15 tools. We have built in the ability to be able to
16 sit there and look at cables and cable failures on
17 an individual vintage basis.

18 We believe that things like condition
19 based maintenance will help a lot. I mean age is
20 clearly an issue but it is not the issue.

21 So knowing what the condition is. And
22 then looking at diagnostic tools. Luther pointed
23 out the need for diagnostic tools. Cable in
24 particular or any of the other pieces of equipment
25 we have.

1 What we really want from a diagnostic
2 tool perspective is a tool that can be utilized on
3 line as opposed to taking outages. Customers are
4 already experienced in outages and so what we
5 would really want as far as sort of from an R&D
6 ideal perspective is a diagnostic that can be
7 utilized on line. Avoid the taking it out of
8 service for test and the development of analytics.

9 So we believe that really those four
10 things really are going to help us and have shown
11 some real help and aid for us at SDG&E
12 particularly with regards to overall system
13 reliability statistics.

14 So we actually have a fairly, we've had
15 a fairly aggressive practical cable replacement
16 program since the early 2000s, somewhere
17 approaching a hundred miles a year.

18 And our original focus was on the main
19 feeder cables. That's where typically the impact
20 on customers is largest. But what we're seeing
21 now is that we have replaced a lot of that cable.
22 And so it's all relatively new.

23 Where we're seeing the failures now is
24 our laterals or branches where we have a much
25 smaller amount of customers.

1 So this graph here now, it's a few years
2 old but it basically sits there and looks at to
3 compound the problem, you can see here the three
4 different curves.

5 And you've got all employees and you've
6 got union and non-union. And what we're seeing is
7 that a significant amount of skilled employees are
8 retiring.

9 And so really, the real issue is how to
10 transfer the knowledge, how to improve
11 productivity and how to, and we believe again, the
12 solution is tied to use of new technologies and
13 use of automation and other investments in R&D.

14 One of the things that we're also seeing
15 is, particularly for power engineers, there's
16 really not a large amount of power engineers
17 coming out of the university systems these days.

18 So what we're seeing is, we're going out
19 and hiring new graduates as opposed to experienced
20 employees. We have a difficulty doing that
21 because when they come to California they all sit
22 there and say, you want to pay me how much, look
23 at the house costs.

24 And so we get them out there. We get
25 them out for the interview. They have a nice time

1 in San Diego and then they turn around and say,
2 you're not going to pay me, you know, 200,000
3 dollars a year, guess what, I'm leaving.

4 The other thing that we're seeing lately
5 is that a lot of the young engineers that we have
6 brought out get five or six years of experience
7 under their belt and then they start to get
8 scavenged by other either utilities or other
9 vendors or other business streams that need
10 experienced employees.

11 Well let me switch gears a little bit to
12 distribution automation. Particularly we're
13 talking about in this particular case, SCADA.

14 You can see here these are our numbers
15 sort of at the end of 2006. But I think one of
16 the key points to take away from this and I'm not
17 going to read all the points here but, we use it
18 to help plan and design. And we use it to
19 remotely operate. So from a system operation
20 reliability perspective we think that that is very
21 important. And we can use it also to diagnose and
22 solve system problems.

23 We started our SCADA installations in
24 '95 with a significant wrap up in '99. We have a
25 preferred design that basically is a SCADA auto

1 substation circuit breaker. And it's called one
2 and a half design.

3 We've got a mid point service restorer
4 on SCADA and an open tie on SCADA.

5 And I think as everyone has pointed out
6 one of the big differences between distribution,
7 transmission is that the network versus the open
8 loop design that is typical of distribution.

9 So we feel that with an open loop with a
10 circuit tie to adjacent circuits in most cases
11 we're able to pick up customers when there is a
12 fault. And so we can minimize the impact to
13 customers.

14 Also what we believe is that we're in
15 the process as Luther also mentioned of doing
16 automation trials where we'll actually fully
17 automate the switching that occurs.

18 Today given historical reasons and
19 safety reasons our operators are very reluctant to
20 actually switch automatically a closer or a
21 breaker that may have opened. They will typically
22 call for a trouble men to get out there.

23 And the trouble men will then sit there
24 and tell them where the problem is, where the
25 fault is. And tell them whether it's safe to

1 restore service via a SCADA device.

2 In some instances of course what that
3 adds is additional time to get the manpower out
4 there.

5 And at the transmission level and
6 substation level that's actually really
7 problematic for us because we have bus ties
8 between adjacent banks and because of the risk of
9 bus fault in the substation we will actually send
10 a crew from our Kearney Substation Operations
11 group to the substation to check and make sure
12 there wasn't a bus fault before we actually close
13 that bus tie and pick up load.

14 That's typically like a half hour
15 operation given our service territory or longer.

16 One of the other things that we see with
17 automation is that it will in the future allow
18 better integration and control of various DER
19 alternatives that are out there both from a SDG&E
20 utilization perspective but also a better
21 integration of customers into the system to allow
22 all the future opportunities that we see are
23 coming down the road for customers.

24 One of the keys about distribution
25 automation is not just, it's not just the

1 switches. It's all the other stuff as well.

2 There's the sensors, the systems, the
3 analytical capability behind it which to a large
4 degree hasn't necessarily evolved to the point
5 where like I said, we're just starting down the
6 automation path.

7 But we've got a lot of SCADA out here
8 already. Why don't we have a system in place
9 today that doesn't operate in an automated
10 fashion? Because of some of the issues with
11 regards to the analytical capabilities and putting
12 that in place.

13 And then one of the other things that we
14 will be doing with distribution automation as well
15 and some new systems that we're putting in place
16 is the inclusion of the AMI data imports.

17 So we see that as enabling us to better
18 isolate those customers who are upstream of a
19 faulted section and can be restored.

20 So I did mention the fact that we do
21 have quite a bit of communication control
22 technologies within our system. We do have
23 extensive radio, microwave, satellite, telephone
24 and fiber optics.

25 We have in the last couple of years

1 piloted five first generation broadband over
2 power-line technologies in San Diego.

3 We are currently embarking on a five
4 year installation of a fiber network between
5 substations to better allow high speed
6 connectivity between basically the relays within
7 the substations themselves.

8 We see that there are some real future
9 challenges for both AMI and Smart Grid
10 applications for communications.

11 One of the real keys I think is just the
12 whole interfaces to new, actually to both the new
13 and the legacy systems and particularly the legacy
14 systems.

15 We've got an installed base that is
16 typically looked at as being a 30 or 40 year of
17 lifetime. We are clearly not turning those over
18 in any appreciable time frame that would renew the
19 system in five years.

20 It's going to be a much longer term
21 issue. So the question is you've got all this
22 older technology sitting out there and if I want
23 to put sensors and I want to automate and I want
24 to do partition based maintenance, how do I get on
25 to that equipment. And then how do I get it back

1 to the systems, the numerous systems that we're
2 going to put in place.

3 And then just as you are aware the whole
4 issue with regards to open communication centers.
5 How is that done?

6 One of the big differences between the
7 sort of power system if you will, versus the
8 communication systems and IT systems is just the
9 fact that there is such a rapid refresh of
10 technology.

11 Our IT people are talking about a total
12 network refreshing of just five to seven years.
13 So the question is given that how do you actually
14 go ahead and make sure that the next generation of
15 technologies that you actually put in place will
16 be able to pick up and take over where you were
17 before. And so open communication standards is
18 the key.

19 This is a little bit of a busy graph but
20 I did want to provide a little bit of information
21 here. This is just for the people that are out
22 there this is the historic, what we're calling DG
23 applications in San Diego County.

24 And I've put it in here just to provide
25 some level of visibility as to where DG

1 installations are and in particular DG sort of
2 classified as ten megawatts or less and primarily
3 in this case gas fired.

4 Because from a numbers perspective the
5 photovoltaic installations in San Diego County far
6 exceed the DG installations.

7 But the predominance of and this is
8 supposed to be the year and this is supposed to be
9 the number, pretty amazing enough people looked at
10 this and that one still got through. What we see
11 is a predominance is in the less than 500 kilowatt
12 range.

13 And then the next biggest one is in the
14 thousand kilowatt range. So a lot of relatively
15 small particularly CHP kind of applications.

16 I pointed out here in particular and now
17 looking at it from a SDG&E perspective I point out
18 Public Utilities Code Section 353.5.

19 And the reason I did that is because it
20 does have a mandate in there that the utilities
21 look at DER alternatives to provide the lowest
22 cost solution.

23 We at SDG&E really do take that to
24 heart. We have developed electrical standard
25 practices to look at incorporating DG as a an

1 alternative. And it's actually based upon our
2 mobile, rental mobile generators which in many
3 respects is actually the lowest cost kind of
4 technology that would compete against a wire
5 solution.

6 Some of the other things that we have
7 done. In our last rate case filing we implemented
8 a program called Sustainable Communities. It is a
9 bigger, broader based than just strictly energy
10 from SDG&E or electricity. It's also on water.
11 It's also on sewage. It's basically whole
12 building design standard practices.

13 And we were able to get that funded
14 through the CPUC. And what we have done with that
15 is we have looked at evaluating alternative
16 distribution service models with this particular
17 program.

18 And we've been looking at in particular
19 minimizing growth opportunities for these
20 particular areas where it's gone in about
21 optimizing energy efficiency and demand response
22 opportunities.

23 We also have put in a lot of
24 particularly renewable resources. Photovoltaics
25 has been the primary resources that have been gone

1 in these communities.

2 I'm not going to go into any great
3 detail about energy efficiency programs or demand
4 response programs only to mention that we do have
5 third parties active in both of those programs.

6 We also do have third parties that are
7 actually aggregating generators as well as loads
8 as part of demand response programs.

9 As you are aware we did get a positive
10 decision from CPUC on April 15th authorizing a 572
11 million dollar expenditure for RAMI. Part of that
12 it was an all party settlement.

13 Part of what happened in that all party
14 settlement and subsequently approved by the CPUC
15 is the installation of remote disconnects and/or
16 load limiting devices on all residential
17 customers.

18 And we see from a distribution system
19 operation perspective opportunities to use those
20 technologies to better optimize how our system
21 performs.

22 There was also a requirement for home
23 area network which is yet to be defined. So we
24 see that again as an opportunity to get into the
25 customer via the meter to be able to provide them

1 signals and information that will allow them to
2 better control their loads.

3 And then lastly a couple of things.
4 Greenfield development, we're actually currently
5 working with a large development in our service
6 territory where they are looking again at trying
7 to expand the whole sort of sustainable
8 communities program to encompass not just a
9 building or two but the whole community that is
10 going in. And it's on the order of 14,000
11 residential homes.

12 And so we are working with them to
13 provide various alternatives standard electrical
14 service that we would give them. And it's been
15 going on for a while and we're very excited about
16 the possibilities of doing some interesting things
17 there.

18 And then lastly sort of on the R&D front
19 in this area we have developed some microgrid
20 proposals that we are moving forward with.
21 Particularly we intend to file that with the DOE.

22 And that we are also involved in the
23 state technologies advance collaborative, the EPRI
24 demonstrating incentives for electricity providers
25 to integrate DR.

1 A real quick discussion of San Diego
2 Smart Grid Study. As I said we jointly funded
3 this with the Utilities Consumer Action Network.
4 John is going to talk a lot about this.

5 We provided all the as is data. And
6 then John and the SEIC team went forward and then
7 carried the work forward to develop the business
8 cases.

9 From an SDG&E perspective we were
10 looking to basically given all of the O&E modern
11 grid efforts and all the telegrid concepts that
12 are out there we wanted to look at really where
13 are we relative to all these efforts and take a
14 look and see where should be heading down, what
15 path should we be heading down.

16 As I said we really view that the
17 utilization of technology to address manpower
18 system design and operations is going to be key to
19 being successful in the future and providing
20 highly reliable service to our customers.

21 And I think generally what we found is
22 that conceptually we really agree with the
23 direction that's laid out in that report.

24 From our perspective the only issues
25 that we really have is the questioning of the

1 business case reliability. We have been going
2 through a whole pile of business cases lately and
3 it really just gets down to the question of is it
4 really a viable case in this point in time.

5 Now this time I'd like to change gears a
6 little bit here. We've talked, Luther has talked
7 about this, Russ has talked about this.

8 What we have done given some of our
9 predictive reliability assessment tools and given
10 where our SAIDI, SAIFI, MAIFI those you asked
11 about industry wide standards reporting measures,
12 those are them.

13 We're currently in the first quartile
14 nationwide. We have a PBR in place. And every
15 time we go for a rate case in the PBR the values
16 of the targets for the PBR reliability measures
17 gets ratcheted down.

18 And we began to wonder, well is that a
19 good thing? Are we at a level where which maybe
20 overall system reliabilities adequate but what
21 about the actual individual customers?

22 We did some focus groups. You're going
23 to see not only what is here, satisfaction
24 decreases the number of outages and the duration
25 of outages.

1 But what we did we contracted with KEMA.
2 And we did some work with regards to focussing
3 more attention on actual customers. And so what
4 this graph really shows you is here, is this is
5 the percentage of customers on our system. And
6 this is the percentage of SAIDI.

7 And it's for the year 2004. But one of
8 the things that we found which is very interesting
9 was that 42 percent of our customers experienced
10 100 percent of the SAIDI minutes.

11 So for all the outages that an SDG&E
12 service territory for 2004 only 42 percent of the
13 customers were actually impacted by those. The
14 rest had no impact whatsoever.

15 And if you actually take a little closer
16 look at it what you find is that 10 percent of the
17 customers experience 60 percent of the SAIDI
18 minutes.

19 For us that was pretty illuminating
20 because we're used to working on a system level
21 used to trying to shore up the system, chasing
22 after system reliability impacts. But what you
23 see here is that individual customers particularly
24 certain individual customers are really seeing a
25 lot of the particular outages that occur.

1 And so we believe that we will improve
2 our customer satisfaction by focussing and by
3 putting our efforts on this. And so we have
4 actually proposed a new reliability indices to
5 both the IEEE Committees, Reliability Committees
6 as well as we have proposed it in our general rate
7 case to measure an alternative index.

8 And that basically looks at, it's called
9 SAIDED and it looks like a reliability above the
10 SAIDI values above a threshold. In our case we
11 have picked a threshold of about 150 minutes.

12 So we would have PBR rewards and
13 penalties tied to impacting clearly those 10
14 percent of customers and the additional ones as
15 well.

16 And so to follow along on this, why are
17 we looking at this? Why are we thinking about
18 this?

19 This comes directly from one of the
20 distribution automation reports that was recently
21 developed for the CEC. And this just shows you
22 the range of values service estimates.

23 And I believe this was in California.
24 And you can see the large variability. And so the
25 question that we asked ourselves is, as we move

1 forward and we think about customer reliability,
2 should there be differentiated levels of service
3 or should each customer expect the same level of
4 service. We haven't answered that question.

5 We also asked well what are customers
6 willing to pay? Typically what we have seen is
7 that while some of these numbers may fairly large,
8 when it comes to actually going to a customer and
9 saying, well I can give you widget X and that will
10 improve your reliability 50 percent. Are you
11 willing to, how much are you willing to pay for
12 that? The answer is typically very small.

13 And an example of something like this is
14 that BC Hydro is utilizing differentiated values
15 of service for capital expenditure optimization as
16 part of their asset management program. And it
17 has been approved by their regulator in British
18 Columbia.

19 So to conclude I think you've heard we
20 as utilities and particularly at SDG&E really
21 believe that the whole aging infrastructure
22 requires a long-term continual investment. If we
23 don't do that we're going to be chasing various
24 problems and put out various fires.

25 But what that also requires is a broad-

1 based, long-term support from all the stakeholders.
2 Because absent that broad-based, long-term support
3 we'll be forced to focus on some areas that will
4 be to the detriment of the distribution system.

5 The other question really is we believe
6 that the differentiated reliability levels of
7 service require an additional investigation. We
8 would really be good to get what level of
9 reliability is enough or is there an enough?

10 We also believe that pilots of
11 technology which are currently not cost effective
12 require rate recovery. And we also think that
13 given some of this market rate issues and this one
14 is not on here but when we added and accelerated
15 depreciation schedule for Smart Grid technologies.

16 As I pointed out one of the issues is
17 that typically the book life of most of the assets
18 of you would think of are on the order of 30 or 40
19 years.

20 We've got refresh rates of IT hardware
21 of seven years. Clearly recovering those
22 investments over that long period of time is
23 clearly not appropriate but there's also sensors
24 and other kinds of technologies that will be put
25 in place and that will be continually renewed.

1 And we really believe that that does require some
2 changes to some of the accounting rules.

3 And that we also believe that more R&D
4 is required to address new technologies and
5 address operational needs. We see that as a
6 cornerstone of being able to provide reliable
7 service to our customers.

8 And I would like to thank the
9 Commissioners for their support of our filing, our
10 GRC filing. And with that I'm open to questions.

11 ASSOCIATE MEMBER GEESMAN: Thanks Tom,
12 that was quite interesting. I wonder if you would
13 elaborate a little bit more on your concerns about
14 the viability of the business case in the Smart
15 Grid Study.

16 DR. BIALEK: Sure. If you look at --
17 And, you know, I'll let John speak to what's in
18 there. The Smart Grid Study takes the DOE sort of
19 modern grid vision and basically, you know, the
20 business cases are out I believe 20 or 30 years.

21 And the real issue is, with some of the
22 business cases we're doing now on technologies
23 today to try to implement, what we're finding is
24 that some of the technologies and solutions that
25 are in the Smart Grid Study at this point in time

1 aren't available or are very high cost. So some
2 of the revalidation of business cases we have done
3 is we have found costs have gone up, benefits have
4 gone down.

5 The overall, from a societal perspective
6 the business case looks really good. We're
7 thinking about more from our internal stakeholder
8 perspective where we have to justify to our
9 shareholders a recover of our costs.

10 ASSOCIATE MEMBER GEESMAN: And my other
11 question was whether you have quantified the
12 workforce ramifications of a much greater
13 automation of the distribution system?

14 DR. BIALEK: The answer to that is to a
15 certain degree yes. As part of some of the
16 business cases we are doing for some of our own
17 internal initiatives we are looking at the costs
18 and the benefits. And clearly what we see is if
19 we do nothing part of the expectation is that we
20 are going to have additional, require additional
21 staff.

22 Let's take distribution system
23 operations as an example. The amount of switching
24 that we intend, we expect to do is going to
25 increase significantly. However, without

1 automation we currently have a manual process. So
2 you can imagine what that means is that as that
3 ramps up we need more people.

4 Well we expect that through automation
5 of those systems through new technologies that
6 we'll be able to levelize, increase productivity
7 and basically keep the staffing levels as they
8 are, or perhaps even decrease them in some areas
9 and transfer people around.

10 ASSOCIATE MEMBER GEESMAN: And have any
11 of those assessments been made publicly available?

12 DR. BIALEK: No.

13 ASSOCIATE MEMBER GEESMAN: Okay. Thanks
14 very much.

15 PRESIDING MEMBER PFANNENSTIEL: Just to
16 follow up on that question. So those haven't gone
17 into a PUC --

18 DR. BIALEK: No.

19 PRESIDING MEMBER PFANNENSTIEL: -- GRC
20 filing --

21 DR. BIALEK: No, they have not.

22 PRESIDING MEMBER PFANNENSTIEL: -- but
23 they will, one assumes, for your next go around.

24 DR. BIALEK: Correct, yes.

25 PRESIDING MEMBER PFANNENSTIEL: This is

1 a blue card, I think it's for the next discussion,
2 though. I think it's the 11 o'clock panel
3 discussion.

4 MS. KELLY: Okay, fine. Anybody on the
5 telephone have a question? Hearing none --

6 PRESIDING MEMBER PFANNENSTIEL: Let me
7 just make sure. This is from --

8 MS. KELLY: Sorry, Nora Sheriff.

9 PRESIDING MEMBER PFANNENSTIEL: Did you
10 want to speak to this panel? Do you have
11 questions for this panel?

12 MS. SHERIFF: No, for the 11 a.m.

13 PRESIDING MEMBER PFANNENSTIEL: Okay,
14 that's what I thought, thank you.

15 MS. KELLY: Thank you. I'm finally
16 getting this and the lights.

17 Our next speaker is John Westerman.
18 Mr. Westerman is a senior program manager in
19 SAIC's energy consultant practice. He has more
20 than 18 years experience in the development,
21 evaluation, application and testing of energy
22 technologies.

23 Over the last two years he was chairman
24 of the San Diego Regional Chamber of Commerce
25 Energy Committee and he is one of the coauthors of

1 the San Diego Smart Grid, Mr. Westerman.

2 MR. WESTERMAN: Thank you very
3 much. This study was funded by SDG&E and UCAN.
4 And the objective of the study was to answer the
5 fundamental question is does it make sense for the
6 San Diego region and the utility in that region to
7 pursue a Smart Grid. And what the benefits would
8 be.

9 This study was intended to be a very
10 first look at answering this question. A lot of
11 the things are very conceptual and but the
12 question was does it make sense and to develop a
13 roadmap to get there and identify a method of
14 implementing a Smart Grid.

15 So I'm going to go to the end of the
16 story first so we can see what the answers are.
17 And then I'll tell you how we got there.

18 The study identified a portfolio of
19 technologies to be implemented that showed a
20 significant savings by implementing the Smart Grid
21 technologies.

22 The results had annual of about 141
23 million dollars per year. And over a 20 year life
24 we quantified the system benefits and the societal
25 benefits.

1 And part of the philosophy of the study
2 was to look at if a Smart Grid is implemented it's
3 not only for the benefit aren't only for the
4 utility but they're for the region as a whole in
5 terms of better reliability, job development,
6 fostering high tech industry in the region.

7 And so we felt that the societal
8 benefits were very important because there are
9 secondary benefits that are outside of the utility
10 that are realized through the system.

11 The estimated capital costs was 490
12 million dollars and the estimate of about 24
13 million dollars for O&M of the grid over and above
14 what would typically be expended because of the
15 Smart Grid technologies.

16 So the conclusion of the study was that
17 the benefits can be achieved and that a Smart Grid
18 does make sense for the San Diego region.

19 Our methodology of how we got here the
20 premise of the Smart Grid is from the Modern Grid
21 Initiative. We decided that we're going to take
22 the initiatives from the DOE Modern Grid
23 Initiative and apply those to the region.

24 And we started with what the objectives
25 are in the San Diego region and SDG&E and did a

1 study of the as is status of what's in the region
2 and what's planned. So we said, here's the status
3 quo and here's what's being anticipated to happen
4 and then brought all of those together to look at
5 development of scenarios as to whether the Smart
6 Grid makes sense.

7 And from that, from the scenario
8 analysis we did a Gap analysis from, here's what
9 we have and here's where we want to be and
10 developed a portfolio of technologies and a
11 roadmap for implementing them. And then did a
12 cost-benefit analysis as to what the economics
13 looked like. And then made recommendations as to
14 what would have to happen in order to bridge the
15 gap and to start developing this Smart Grid.

16 So the major findings we had for in the
17 current status of San Diego is that as Tom
18 displayed in his presentation there is a growing
19 population of DG both gas-fired and PV in the
20 region.

21 One of the things we're look at as a
22 Smart Grid is you look at what's at the end of the
23 distribution and look at resources as far as what
24 the customer is doing, what they need and how
25 they're impacted along with out of region

1 generation and how you get the electricity from
2 where it's generated to the end points.

3 We also identified that the existing
4 communication infrastructure that the utility has
5 isn't sufficient to support the amount of
6 communication that's required in a Smart Grid.
7 Because when we're talking about a high deployment
8 of sensors, communication between devices and
9 there will be a significant investment requirement
10 for the communication.

11 One of the fundamental things that helps
12 support some of these things is that we took into
13 account the AMI project and that's an assumed to
14 be going to be implemented in our study. So that
15 is one of the building blocks that is you don't
16 see it the study as something that is funded
17 through the study because it was already projected
18 that it was going to go in.

19 And in doing the analysis we had to look
20 at the filing, the AMI filing to identify those
21 benefits that SDG&E was already projecting through
22 the AMI project to make sure that we weren't
23 double counting the benefits from the technologies
24 that we were planning on implementing through our
25 study.

1 SDG&E also has some substation
2 automation programs in progress. Some field SCADA
3 switch roll out programs and the BPL demonstration
4 project.

5 One of the other things that we felt in
6 the study that really helped facilitate the
7 benefits of a Smart Grid is the California Loading
8 Order.

9 Because by utilizing energy efficiency,
10 renewable power and demand response those things
11 really help facilitate, they're another tool in
12 optimizing the operation of the grid.

13 So I'm going to go back and forth a
14 little bit here. Under our scenario analysis we
15 identified three areas of impact looking at
16 economics in the region, environmental regulation
17 in the region and then technology development.

18 And under each of those categories we
19 looked at the extremes for the economic
20 development from a blue sky everything is hunky-
21 dory and everybody is happy to recession where
22 businesses are leaving town.

23 And we did an analysis to identify those
24 drivers that impact the grid under each of these
25 scenarios.

1 And when we did that we had a focus
2 group of people working on quantifying on a scale
3 of zero to ten whether the extremes in each of
4 those areas would make a case for a Smart Grid
5 when we're trying to answer our question, you
6 know, does it make sense for the region to pursue
7 a Smart Grid.

8 So we see that the blue sky and the
9 breakthrough technology are right on the fringe of
10 being able to substantiate a case for a Smart
11 Grid. Where the high level of environmental
12 regulation is not, doesn't make a strong case for
13 or it doesn't, it's in the middle. So you would
14 have to have other reasons to justify going
15 forward with a Smart Grid based on if you're in
16 this region.

17 And then the last three were found to
18 have not to make a strong case or not a case at
19 all for moving forward with the Smart Grid.

20 And so when we go back to what we
21 forecast for the San Diego region we forecasted
22 continued economic growth, high level of
23 environmental regulation and anticipation of
24 fairly rapid technology development.

25 And we saw trends in regulation that

1 would increase the, further increase the
2 installation of renewable energy, the use of
3 alternate fuels as well as higher levels of energy
4 efficiency and demand response.

5 The other thing with San Diego, we
6 looked at the business climate in San Diego. San
7 Diego doesn't have large industry. A large number
8 of industrial customers. Most of them are
9 smaller, they're large commercial customers but
10 they're not real energy intensive. There's not
11 oil refineries. There's no car manufacturing.
12 It's mostly the profile follows more of an office
13 building type of application.

14 But there's a lot of high tech
15 businesses in San Diego that require high levels
16 of power quality, high levels of reliability
17 especially in the biotech sector where they have
18 experiments going on that if they get out of their
19 control conditions which could be caused by power
20 irregularities that there's a significant cost in
21 their development processes that are sacrificed.

22 So when we got to the Gap analysis we
23 looked at the, we're looking at these as a pyramid
24 of how you build the grid and implement the
25 things.

1 And theses here are directly from the
2 Modern Grid Initiative called the Key Technology
3 Areas. And so this represents where we want to
4 be. This represents where we are right now.

5 And you can see that we have sensing and
6 control devices. And here we have sensing,
7 metering and measurement. And on the Smart Grid
8 the number of sensors, the number of measurements
9 and metering is a lot higher than the current
10 state.

11 And so when we are looking at building
12 the portfolio for a Smart Grid we're looking at
13 building the base, installing these grid
14 components that allow you the flexibility to do
15 various things on the grid. And once those are
16 installed then we're adding the sensing, metering
17 and measurement and then the communications and
18 the control methodologies on top of that and
19 finally with all the sensors being read and all
20 the control algorithms on we're adding some
21 decision support and human interface components on
22 top of the pyramid in order to visualize control
23 and to make sure everything is integrated in an
24 optimal manner.

25 So this is a list of the attributes of a

1 Smart Grid. Basically we're looking at the
2 ability to detect and address emerging problems
3 before they impact service, make protective
4 relaying the last line of defense and not the only
5 line of defense.

6 Respond to local and system-wide inputs.
7 Incorporate extensive measurements and rapid
8 communications. Automatically adapt protective
9 systems to accommodate changing conditions. Re-
10 routing of power flows and changing of loads.
11 Improvement of voltage profiles and the ability to
12 take corrective steps in a matter of seconds.

13 Again we're looking at enabling the load
14 to distributed resources out at the end of where
15 the customers are located.

16 We're looking at improving reliability
17 and security. And then again the top of the
18 pyramid with the system operators advanced
19 visualization tools that help provide the human
20 oversight that's required for the operation.

21 When we did our Gap analysis we
22 identified 26 what we called improvement
23 initiatives to be implemented as a Smart Grid.

24 And out of the 26 we narrowed it down to
25 these 13 that our project team identified as what

1 we thought was the best approach for implementing
2 the Smart Grid.

3 And you can see that we have a group
4 that is three areas of communication because we
5 were looking at Ethernet over Fiber is addressing
6 the long-haul communication. The 4G WiMAX is
7 looking like at mid-haul communication. And then
8 the Zigbee/WiFi - Wireless is the short haul.

9 And this is where we're looking at the
10 ability to have the device inside the AMI meter to
11 be able to reach into the home or the customer's
12 business to control end use devices.

13 And we think that the integration of a
14 number of these technologies was a better approach
15 than having just one communication approach for
16 the program.

17 The other thing is that it's obvious
18 from this that we came up with 26 initiatives is
19 that there's not one silver bullet that's being
20 identified that's going to solve all the problems
21 on the grid.

22 It's going to be a portfolio approach
23 and it all has to be integrated in a smart fashion
24 so that we have a network system that's adaptable
25 and high performing.

1 So we looked at in our business case
2 where the benefits come from implementing those
3 technologies. And the list is here and the top
4 four that were identified where most of the
5 savings came from were the highest one the
6 reduction in forced outages.

7 The second one was an increase in job
8 creation. Again this is a societal benefit. But
9 when you look at the potential for technology
10 development the number of people it's going to
11 take to implement the system and operate once it's
12 going there's a significant job creation growth
13 through this program.

14 The third is reduction in peak load.
15 And this is not a demand response reduction. It's
16 a an increased efficiency reduction.

17 And then the fourth one was the
18 reduction in congestion costs. Now in our study
19 the reduction in congestion costs we were looking
20 at significantly reducing the current RMR costs
21 but those expire after a number of years.

22 And so the value in reduction of
23 congestions costs are higher in the near term than
24 they are out years.

25 Once we identified the portfolio and we

1 had the costs and we had the benefits associated
2 with them the next thing we did was to look at how
3 you would phase in that portfolio of improvement
4 initiatives and what approach you would take.

5 We came up with three scenarios. One is
6 the earliest positive cash flow. And in this
7 scenario we looked at starting at the bottom of
8 the pyramid and building things in phases and
9 trying to get the highest return or positive cash
10 flow from the early investments so that we could
11 use the savings to pay for future investments.

12 The second one is maximum benefits
13 early. And this is basically putting, installing
14 the infrastructure that gives us the biggest bang
15 for the buck as soon as possible so that the
16 benefits start accruing the fastest.

17 And then for each of these scenarios you
18 can see that the internal rate of return and the
19 NPV will vary. And for the optimized IRR case we
20 were sliding the phasing of the improvement
21 initiatives around until we found an optimized
22 level of between NPV and the IRR.

23 But you remember we have a lot of
24 footnotes here as to what we're talking about as
25 far what the IRR means and that these numbers vary

1 significantly from what SDG&E would realize if
2 they had to fund these under the current rules of
3 engagement for recouping their investments and
4 getting them approved through the CPUC process.

5 So this is the San Diego region benefits in
6 economics.

7 So our roadmap for how do we get there,
8 we started with, we're going to move very quickly.
9 We wanted to make sure in the study is that we're
10 not looking to say 20 years from now we to start
11 doing something. We're saying that integrating
12 the Smart Grid technologies there's a lot of
13 things out there that can be done right now. That
14 we don't have to wait for a technology to be
15 developed.

16 Obviously there are some here that are
17 in the early stages of development that we're
18 anticipating are going to be included. But this
19 is actually an aggressive implementation roll out
20 plan where the first phase is used to establish
21 the foundation for the Smart Grid and then start
22 creating the benefits through improved
23 reliability.

24 This scenario here that's shown on this
25 slide represents the middle scenario on the last

1 slide which was the maximum benefits early.

2 And then the second phase, you can see
3 the second phase falls, the dates fall within a
4 subset of the last phase because these are a roll
5 out over the years. And then as we get enough
6 infrastructure after the first couple of years of
7 implementation we can start adding things that we
8 can integrate the consumer systems into the Smart
9 Grid. And then also start providing economic
10 electricity services to further maximize the
11 functionality and the benefits of the system.

12 The next thing that we have is a
13 conceptual idea of some the Smart Grid
14 implementation. So we have the basic what we have
15 now, the substations, the loads at each end.

16 In the phase one we start adding
17 sensors. The AMI is assumed to be interfaced to
18 the customers, start putting in DG at strategic
19 customers, communication systems and the sensor
20 network are installed. We're looking at
21 implementation of some energy storage devices and
22 then some of our control at needed areas.

23 And then in the second phase we start
24 bringing in utility owned DG systems, some
25 intelligent agents for control and optimization of

1 the system.

2 And ultimately we're showing on this
3 grid the conceptual outline of what a microgrid
4 would like with the utility owned DG and the
5 sensors in operation and the energy storage.

6 Again we're looking at another roll out
7 slide kind of reiterates on a case by case basis
8 what we're looking at. We have a number of
9 initiatives that we added. We have asterisks by
10 that have been moved out to accommodate some time
11 for them to be developed or the cost to come down
12 or to be proven through some R&D programs.

13 The four R&D areas that we identified in
14 the study. We recommended doing a WiMAX pilot for
15 the mid-haul communications. A pilot with an
16 advanced energy storage device. And then also
17 looking for a microgrid demonstration project.
18 And then development and testing of these agent
19 software systems that provide some autonomous and
20 smart control systems.

21 Some recommended policy changes that
22 came out of this study. In order for the Smart
23 Grid to be optimized and take full advantage of it
24 we're recommending that we need clear and low cost
25 market signals so that customers can make

1 decisions as to when they want to use electricity
2 and have some incentives for when the cost of
3 utility a lot for the services that the customers
4 have information to be able to make decisions on
5 how to use that.

6 And in a Smart Grid ultimately the
7 customer doesn't have to make a decision in
8 looking at it right there. He has a system
9 already configured and programmed so that when the
10 signal is sent to him he's already decided which
11 things are going to operate or not.

12 We're recommending incentives for the
13 use of advanced technologies that increase
14 capacity or improve efficiency. CEC supported
15 evaluation of economic benefits of commercially
16 available voltage stabilization technologies.

17 Everybody has discussed this so far so
18 the open architecture, interoperability,
19 reliability standards are required. And then also
20 new rate designs.

21 And this is specifically looking at
22 residential customer rates to because right now
23 it's difficult to get the residential customers
24 engaged in doing very much with their load with
25 the current rate structures.

1 And then finally in keeping with our
2 philosophy some way for the utility to take into
3 account some of the societal benefits when they're
4 looking at implementing some of these
5 technologies.

6 And the report can be found at this
7 website here, on EPIC's website if anybody is
8 interested in downloading it and going through all
9 the fun reading there.

10 ASSOCIATE MEMBER GEESMAN: John thanks
11 very much and I certainly enjoyed reading the
12 report when it came out. What's the follow up
13 strategy?

14 MR. WESTERMAN: The follow up is that
15 the ball is in SDG&E's court. The date and my
16 understanding is that they are pursuing several of
17 the R&D programs. There are some other things
18 that I know they're working on but I'm not sure
19 that I can discuss those. But SDG&E is being very
20 proactive and they're taking a hard look at it.

21 They've gone back and looked at our
22 numbers as far as the mostly from the business
23 case I think that the technologies and the
24 portfolio approach. You know Tom has said that
25 they conceptually agreed with that.

1 The next step is given our assumptions
2 in the report and that it makes sense, the things
3 need to be looked at a lot closer. We looked at
4 the number of substations and assumed constraints
5 on so many of them by a certain percentage. We
6 didn't go out and measure them and quantify them.

7 So the next step is to do a more
8 detailed analysis as far as what parts of the
9 infrastructure can be addressed to get the biggest
10 benefits as soon as possible and to get better
11 costs numbers and to basically do a more detailed
12 analysis and to demonstrate some of the benefits
13 through some of these R&D programs.

14 ASSOCIATE MEMBER GEESMAN: And I believe
15 you said that you were involved in the San Diego
16 Chamber. How did they respond to the report?

17 MR. WESTERMAN: Very favorably. The
18 Energy Committee for the Chamber of Commerce in
19 San Diego is very active. SDG&E is very active in
20 it. It's a community of people who are very
21 knowledgeable in the area of energy and are very
22 forward thinking.

23 And most people see that it's not a far
24 stretch of the imagination to think that that
25 resource of the distribution and transmission and

1 use of electricity is more intelligence needs to
2 be and optimization needs to be applied to it.

3 ASSOCIATE MEMBER GEESMAN: You know just
4 to give my perspective on how the process works.
5 Bridging that gap between societal benefit and
6 company interests or benefit on the part of the
7 utility is a challenge. But San Diego, pretty
8 compact service territory and extremely well
9 organized local community, more people and more
10 interests or more entities with interests in
11 energy than I think we see anywhere else in the
12 state. It's really within your capacity to agree
13 as a community that you want to do this.

14 And I'm being loose with what I
15 described as this. But I do think it's within the
16 local community's hands to determine if this is
17 the right way to go.

18 I acknowledge having known them for a
19 long time UCAN can sometimes be a little slippery
20 on that but I think that they've at least
21 indicated an early interest in commitment.

22 If you're able to arrive at that type of
23 general consensus I think the regulatory system
24 will respond pretty quickly and pretty
25 effectively. That's the premise that we've used

1 in so many of our other initiatives over the last
2 several years, the Solar Initiative, the
3 Greenhouse Gas Initiative, our emphasis in the
4 loading order and efficiency trying to capture
5 societal benefits and somehow reconcile that with
6 the utilities' perspective.

7 So I strongly encourage it and if
8 there's anything that state government can do to
9 facilitate that process I don't think you should
10 be hesitant about asking us to do that at all.

11 MR. WESTERMAN: I'm glad to hear that.
12 I think that in my experience in San Diego we
13 always think that we're the little guys at the end
14 of the cul de sac and it's hard to get our voice
15 heard up here a lot is our perception. So I'm
16 glad to hear that.

17 ASSOCIATE MEMBER GEESMAN: There's more
18 strength at the end of the cul de sac if you can
19 get all the neighbors to agree on a general
20 direction.

21 MR. WESTERMAN: Right.

22 ASSOCIATE MEMBER GEESMAN: And I think
23 you realize that.

24 MR. WESTERMAN: And just as a follow up
25 to that in San Diego the organization through the

1 SANDAG group is developing a lot of momentum in
2 that area as well for many energy related aspects
3 for our community.

4 PRESIDING MEMBER PFANNENSTIEL: I have
5 two pretty specific questions on some of these
6 assumptions that you gave.

7 One has to do with the question about
8 rate design as important to give customers the
9 right incentives. Have you started, have you gone
10 to the PUC or has SDG&E gone to the PUC with that
11 recommendation because I, it looks like it's
12 fairly fundamental and I may be wrong but that's
13 how I saw it.

14 MR. WESTERMAN: As far as I know it's
15 only been identified but no active steps have been
16 taken. Some of the things that we envision in a
17 Smart Grid is for instance like power quality,
18 some customers would be willing to pay for power
19 quality but there's not a rate for your high power
20 quality customer and we can charge you more to
21 insure you have your requirement.

22 That would be a rate design that would
23 be in there. And then also for a number of
24 aspects there's not a rate design for capacity,
25 value of capacity for several technologies so

1 those are some of the --

2 PRESIDING MEMBER PFANNENSTIEL: In your
3 cross benefit analysis did you assume that there
4 would be those kinds of rate designs or was that
5 not necessary.

6 MR. WESTERMAN: No there was some
7 assumptions and the biggest assumption on rate
8 design was basically addressing the residential
9 customers. And then also for the value of
10 electricity on the market that could be sold from
11 distributed generation into the grid.

12 PRESIDING MEMBER PFANNENSTIEL: One
13 other question on your assumptions, you showed an
14 increase employment in the benefits in the region.
15 And yet at some level it seems like that may be a
16 net question because with more automation one
17 assumes that SDG&E would use fewer employees on
18 their distribution and maintenance concurrently.
19 So I can see where one would be a higher skill
20 level.

21 But is it in fact net, net warrant more
22 people?

23 MR. WESTERMAN: Yeah, we were looking at
24 not only at the people for implementing and
25 operating the grid but we were looking in being,

1 probably being optimistic that if the San Diego
2 region had a Smart Grid and could demonstrate high
3 reliability, high power quality and the benefits
4 that specifically high tech type companies would
5 want to use that you would draw more businesses
6 into the region. Because we'd be such a great
7 place to live.

8 PRESIDING MEMBER PFANNENSTIEL: I see.
9 You are very optimistic, thank you.

10 MR. WESTERMAN: Thank you very much.

11 MS. KELLY: There's no questions on the
12 WebEx. Telephone participants, do you have any
13 questions?

14 UNIDENTIFIED PHONE SPEAKER: No.

15 MS. KELLY: Thank you.

16 PRESIDING MEMBER PFANNENSTIEL: I see
17 one question here. You need to go to the
18 microphone in order to have that question heard by
19 people on the web.

20 MR. RACHLIN: Sure, thank you. Hi my
21 name is Aaron Rachlin from Borderland Wind in Los
22 Angeles. And John in your presentation you
23 mentioned in the recommended RD&D projects,
24 advance energy storage. I was wondering if you
25 could just give a little bit more detail on the

1 nature of that.

2 MR. WESTERMAN: On that one we're
3 looking specifically at electricity storage and we
4 were looking at battery technologies, flywheel
5 technologies. There's a couple more but there in
6 the portfolio of the Modern Grid. There's a whole
7 group of energy technologies that are in that
8 bucket that are being looked at.

9 And we feel that at some point one of
10 those is going to emerge as a viable technology to
11 be implemented into the system.

12 MS. KELLY: Thank you. The next part of
13 our agenda is a panel discussion. And what I'm
14 going to do is that I have a number of questions
15 that I have posted in the agenda. I'll join the
16 panel members there. We'll read off a number of
17 those questions and then what I'd like to do I
18 think because they do ask about utility investment
19 if we could start maybe at the bottom of the cul
20 de sac now and have Tom and just go, Luther and
21 Russ respond and then John Westerman and Eric
22 Lightner I've asked to join us in this discussion
23 because he brings a perspective from DOE. And the
24 whole modern grid concept started with DOE.

25 So I feel like Eric's organization is

1 the father of this activity or the mother. So I'm
2 just going to join them at the table. And then I
3 will start with the first question and this is
4 meant to have an interactive summary type
5 discussion.

6 Each of these presentations has
7 suggested we want to do this, we'd like to do
8 that. I'd like to just focus in on what some of
9 the priorities are. What they're doing now and
10 what we're looking for in the future.

11 Okay, the first question, California
12 utilities are investing at record levels in new
13 and old distribution systems. Russ I think gave
14 us an idea of the numbers are in the billions.
15 And this is a substantial investment that will be
16 with us for quite a while.

17 And so most of this material as I think
18 actually Luther said has long life, at least 10,
19 15, 20 and 30 years. So I think it's very
20 important to begin discussion about what we're
21 doing today and how it's going to serve us in the
22 future so we can plan for that future in advance.

23 So the first question I had and I'm
24 going to put the first two goals together to Tom.
25 What components and designs are being used and

1 will the distribution systems built today support
2 the environmental and sustainable energy goals
3 that California has established.

4 In particular I'm thinking of the
5 renewable portfolios standards, CHP integration,
6 demand response and now more recently CO2
7 reductions.

8 DR. BIALEK: One of the things, one of
9 the things that maybe I didn't mention when we
10 talked about the Smart Grid, conceptually like I
11 said we, SDG&E agree that that's probably the path
12 we're headed down. You've been headed down that
13 path anyway.

14 So when you say what components and
15 designs are being used, I mean traditionally we
16 know what a transformer looks like. We know what
17 a cable looks like. We know all these bits and
18 pieces of equipment, the manufacturers are out
19 there developing new technologies. We are looking
20 to try to incorporate those new technologies and
21 designs into our systems.

22 In a meeting we had the other day one of
23 the things that we talked about was just a whole
24 rejuvenation of the systems and implementation of
25 new systems in place to try to achieve as I said

1 it earlier the high level service reliability to
2 our customers with a maturing workforce, different
3 skill sets.

4 And so I would say that we're doing the
5 best we can with technology that exists today
6 because first off if you look at what the
7 technologies that are out there that people are
8 offering you'll see there are variance on what we
9 have today. Some have some more advanced
10 features.

11 One of the difficulties we face with
12 some of that is as the manufacturers are
13 developing products what they are doing is
14 basically obsoleting their earlier generation of
15 technologies and so for one particular vendor we
16 have six different versions of a controller and
17 none of them are backward compatible.

18 So you get into those kinds of issues.
19 But I would say that in general we are taking a
20 look out there. We have given this study, given
21 our participation in the DOE Modern Grid
22 Initiative we believe we're looking forward and
23 trying to implements systems in place that will
24 try to get at supporting the state policy goals.
25 And that's really where we're headed.

1 And I see that as time goes on that we
2 will able to do things with these systems in place
3 like AMI and a lot of the automation that weren't
4 envisioned ten years ago. But we did start
5 putting them in place.

6 And so it's not a total, it's starting
7 to, our system is starting to morph from a 1950s
8 vintage into a much higher technology kind of
9 environment. And we just see that continuing.

10 MR. DOW: I'm like Tom. I think the
11 design of the technologies are being made by the
12 manufacturers and we're utilizing those. Where I
13 see us doing some of a lot of work is in the area
14 of how do we design our system differently using
15 our current technologies.

16 Or what new technologies do we need so
17 we can encourage and support the, for example,
18 solar homes. What does a subdivision lay out look
19 like for a hundred percent penetration of solar in
20 a new home.

21 We don't know what it is. We don't know
22 what how all those are going to interact. And so
23 we're redesigning our systems on how we think it's
24 going to be. And so we're going to have to do a
25 lot of careful monitoring of that to make sure

1 that that's, that we provide the service that we
2 need to provide.

3 I think we are doing what we have. I'm
4 not sure everybody knows what it's going to look
5 like yet. So we have to stay with it.

6 ASSOCIATE MEMBER GEESMAN: Do you think
7 that there is a market demand out there for
8 differentiated level of service at the
9 distribution level?

10 MR. DOW: Is there a demand, I think it
11 is probably at the commercial level perhaps. But
12 I'm not sure at the residential level.

13 ASSOCIATE MEMBER GEESMAN: But you'd say
14 that in today's commercial class you can see the
15 logic of some customer stratification in terms of
16 quality of service?

17 MR. DOW: Yes sir.

18 PRESIDING MEMBER PFANNENSTIEL: Isn't it
19 the case where say high tech companies were
20 willing or are willing and actually are paying
21 more for high levels of service?

22 MR. DOW: In some cases they are. They
23 are doing it generally through back up feeds and
24 UPSes.

25 PRESIDING MEMBER PFANNENSTIEL: Oh, so

1 it's not a specific rate design there. But it is
2 a fee based.

3 MR. DOW: Yes, they're looking for a
4 company, we're trying to work with them on excess
5 capacities that they can buy as excess capacity so
6 that they can have a back up.

7 MR. NEAL: When I look at what we're
8 doing in the area of developing the grid to meet
9 these goals I see a couple of things.

10 One, there's are a lot of little
11 incremental improvements. The basic design is
12 still a substation breaker and a radial feed going
13 on out using wires. So it's not dramatically
14 different.

15 But there are continuing incremental
16 improvement in the equipment being used. We
17 mentioned how we're going to upgrade the types of
18 cable, some places where in the past you'd have
19 manually operated switches that were oil filled
20 boxes sitting in underground structures are now
21 going to be perhaps gas insulated but have a
22 vacuum breaker type technology inside which
23 represents an incremental improvement of what you
24 have out there.

25 I would say that the most significant

1 thing that's going on right now that will assist
2 in our environmental and sustainable energy goals
3 is AMI. Because AMI represents the drafting of
4 customer loads into the system scheme.

5 The fact that we'll be able to have a
6 much more ubiquitous communication system out
7 there throughout the distribution system and the
8 ability to reach into customer homes and
9 facilities and perhaps cycle or turn off or modify
10 the behavior of loads during for instance for
11 things like peak shaving, for taking credit for
12 rolling standby energy sources, and even for being
13 able to have that customer load respond to
14 modulate system upsets where you'd be able to say
15 well now we don't, you may be able to, given that
16 you have the ability to make a proportional
17 response, a smooth response of customer load to a
18 system upset you might be able to stabilize some
19 of these upsets without anybody even knowing that
20 you're doing it, without having to build
21 additional transmission lines and so forth to meet
22 these transient contingencies and things of that
23 nature.

24 So I think that the AMI system is the
25 most encouraging thing that I see there. As far

1 as some of the other, you know one thing that I'm
2 observing is that in attempting to meet our
3 renewable portfolio standards and some of these
4 other things there actually coming into
5 realization as concentrated remote generating
6 plants, wind farms, geothermal facilities, places
7 out in the desert where you have acres and acres
8 of solar sterling engines or something like this
9 with a massive transmission upgrades to actually
10 bring those things in.

11 It's not really impacting the
12 distribution system. Or the distribution system
13 is not contributing that much. I'm not afraid of
14 a million solar roofs putting a strain on the
15 distribution system in any way. That will just
16 appear as a modulation to our local load growth
17 and will be accommodated by our normal ways of
18 dealing with that.

19 But given that you have, if you wanted
20 to do more in the area of distributed generation
21 that was, let's say CHP-type things which were and
22 going to be able to use those as a system
23 resources, probably the fact that you'll have a
24 more low-cost, ubiquitous communication system as
25 a side benefit of AMI might make integrating these

1 distributed generators into some kind of control
2 scheme and take you know, a lot of time people
3 talk about the benefits that they have in the
4 distribution system, but a lot of those benefits
5 are hypothetical if you don't really have any
6 communication and control and means of integrating
7 it into your planning.

8 If we get the AMI out there as we are
9 currently envisioning it that situation might
10 change.

11 MS. KELLY: Russ, can you put your
12 microphone on.

13 MR. NEAL: Oh, should I turn it on?

14 MS. KELLY: Yes, please. He said he was
15 hearing you so I didn't interrupt you. Thank you.

16 ASSOCIATE MEMBER GEESMAN: Russ the San
17 Diego Smart Grid Study spoke of utility-owned
18 distributed generation in one of its phases. Is
19 that something that Edison would consider?

20 MR. NEAL: Yes we would consider that.
21 There's a couple of things that impact us there as
22 we've thought about that. I mean it's illegal for
23 us to do it today.

24 When we do a, when we do our annual
25 evaluation of DG as a substitute for a

1 distribution wires investment, we've never found a
2 case where distributed generation whether we owned
3 it or somebody else would be a cheaper way of
4 meeting the distribution, the cost per kilowatt
5 there and there is an order of magnitude or two
6 orders of magnitude difference in many cases
7 between those.

8 But what is the most attractive thing
9 would be if you have, when you have some of the
10 customers who have a particularly attractive
11 combined heat and power application, let's say a
12 hotel or a hospital with a heavy laundry load and
13 things of that nature, schools with swimming
14 pools, things of that nature, the complicating
15 factor becomes that there may be an energy benefit
16 of going with CHP there but the owner doesn't want
17 to get into the energy business of managing, they
18 would just as soon just have a hot water heater
19 going someplace and pay the bill as they would
20 have a rotating machine with emission controls and
21 electrical issues and all that sort of thing
22 that's a headache for the owner.

23 So some third party entities that tried
24 to get into the business of being the, of running
25 and operating those things for the third party and

1 interfacing with the utility, I think if the
2 utility was able to move in and be a generic
3 energy provider, provide both the heat and the
4 power which Edison in particular is not in the gas
5 business so we have not attempted to move into
6 having any kind of a rate where we can sell Btu's
7 of heat to somebody's swimming pool and that we
8 would then maybe own a CHP plant on the customer's
9 premises and so forth and so on.

10 But the idea has been kicked around.
11 And I think it has certain advantages in that you
12 have fewer parties that have to all get lined up
13 to make something happen if the utility was able
14 to do, to say, look we'll provide you your heat,
15 we'll provide you your electricity, we have
16 established rates and we'll just do it whatever
17 way makes sense in this application whether it's
18 with CHP or something else. You know that is
19 potentially attractive.

20 ASSOCIATE MEMBER GEESMAN: I think as
21 you get younger and more entrepreneurial types
22 upstairs in the executive suites that might be
23 perceived as an attractive business opportunity
24 for you. And one that you might find a lot of
25 receptivity among regulators for.

1 MS. KELLY: John you're just there and
2 then we'll come back to Eric.

3 MR. WESTERMAN: Yeah I think that one
4 thing came to mind. I think that the AMI is
5 obviously the great foundation for taking where we
6 are now and moving forward.

7 And it's also taking the utility from
8 transmission and distribution lines to being a
9 huge IT organization because there's a lot of data
10 and a lot of data management to go into that.

11 And the other thing is that I think the,
12 with SDG&E going into incorporating the disconnect
13 capability on the meter that was proved that going
14 back to the energy crises days which I we won't
15 again, but it allows them to have the ability to
16 disconnect at the customer level and not at the
17 feeder level. So there's an opportunity to
18 control that better. So it's a less disruptive
19 solution to the same problem.

20 MS. KELLY: I think I'll just go through
21 the questions and then see if anybody has
22 additional comments on that. Would that work in
23 the interest of time?

24 The next question, Eric has already
25 indicated he has nothing to add to that first

1 question but wanted to add to the second. So I
2 will go over the second question and start with
3 Eric and then we can just move around the table.

4 What are the most significant barriers
5 to creating a modern 21st century low carbon
6 energy network? And to me, I'm going to talk
7 about that in my own presentation. But a low
8 carbon energy network is where a customer, low
9 carbon resources, are integrated fully with the
10 utility system.

11 So what are the most significant
12 barriers to creating this modern system? And we
13 have had some comments on AMI. How will AMI
14 contribute to achieving these objectives? Eric.

15 MR. LIGHTNER: Okay.

16 MS. KELLY: Please give your name when
17 you go around.

18 MR. LIGHTNER: I'm Eric Lightner from
19 the Department of Energy.

20 And I couldn't answer that first
21 question, Linda, because I'm not out there
22 implementing anything. I'm just sitting in
23 Washington DC just like you are sitting here. So
24 I figured I wasn't qualified to answer that first
25 question.

1 But the second question, and I'll expand
2 it a little bit. What are the most significant
3 barriers to creating, you know, more of a modern
4 grid, modernizing the 21st century grid. Not just
5 for the carbon energy network, which is your
6 objective here but, you know, I really think it
7 comes down to not necessarily a technological
8 question. I think it comes down to having the
9 political will to make it happen.

10 And really, you know, raising the issues
11 like we're doing here today, like we did two weeks
12 ago in an event that we had in DC called GridWeek
13 and events like this to really raise the issues,
14 talk about them in public forums. Engage
15 decision-makers at a very high level that these
16 are the issues, these are problems. These are the
17 benefits if we can reach those goals that we have.
18 So I really think it's a matter of raising the
19 awareness to the people back that can make the
20 decisions to make the changes happen.

21 Now that being said I think on the
22 technological side there is one major issue that
23 stands out in my mind that I have heard over the
24 past two years, that I have heard here today, that
25 I have heard again at the GridWeek event. And

1 that's really this whole issue of open protocols,
2 communication protocols and interoperability, to
3 enable interoperability.

4 How can we get devices across the
5 enterprise and between enterprises to really be
6 able to exchange information so that we can act on
7 this information in a much more effective and
8 optimized fashion.

9 Really that's what I've seen. If we can
10 crack that nut, if we can solve the whole
11 interoperability issue I think we'll be able to
12 really see and realize a lot of these benefits
13 that we all believe are just there waiting to be
14 tapped into.

15 DR. BIALEK: Tom Bialek. I would concur
16 with a lot of what Eric has said. But in
17 particular now from more of a utility perspective.

18 I think one of the big things that we
19 see as we go forward is the individual operator or
20 utility employee with we sort of call it
21 information overload. That we see as something
22 that's going to need systems, going to need a
23 whole pile of things in place just to deal with
24 all the AMI information, the sophistication with
25 regards to automation of the system. Again, these

1 aren't in any particular order but, you know,
2 those are some of the issues.

3 We also see that, I would say that one
4 of the biggest things is cost. If you say to us
5 today, how much -- As I said, for us to turn over
6 the entire system it's a huge, it's an
7 astronomical cost. And then not just of the
8 existing, replacing the existing stuff in kind but
9 even some of the newer technologies that are
10 coming out. They're on the borderline of being
11 really commercially available, being commercially
12 viable and so they're also at a very high cost.

13 Another thing I'd point out I think is
14 sort of also the customer acceptance/
15 participation. We have, I think to address your
16 question with regards to rate design, in our GRC
17 phase two we do have rate design issues with
18 regards to critical peak pricing rates for
19 customers. So that is in there.

20 But it's just for their level of
21 sophistication. Today people when we talk to
22 particularly residential customers, the
23 expectation is, I flip the switch, the lights come
24 on. I plug something in the outlet, it turns on
25 whatever. You know, my computer goes, all those

1 other kinds of things. They don't necessarily
2 understand their impact.

3 And even if you gave them a pricing
4 signal they'd be saying, well what do I do with
5 it. They're not sophisticated enough at this
6 point in time, and certainly part of the AMI roll
7 out, the customer education piece I think is going
8 to be something that is going to be really
9 important as things move forward.

10 I think you see the commercial and
11 industrial customers being significantly more
12 sophisticated and ready and willing to embrace the
13 kinds of new technologies that are out there.

14 Also some of the technologies that are
15 sort of envisioned to a large degree are, as I
16 said are, while they are available they're
17 available as onesies and twosies or they're, you
18 know. So there's really a whole level of R&D even
19 on technologies that don't even exist, that are
20 envisioned as to providing solutions.

21 And then with regards to one of the big
22 challenges I think is going to be for clearly
23 photovoltaics and wind. It's just the whole issue
24 with regards to, as you incorporate them, the
25 dispatchability issues associated with them.

1 They're going to be there when they're
2 going to be there. And you're going to have to
3 sit there and look at your system, look at your
4 other generation, move that around. Start
5 adjusting other switches, devices on the
6 distribution system to accommodate them, and
7 that's a totally different model than what we have
8 today.

9 But for us, yes, clearly AMI will be
10 there. We see it providing important audit
11 restoration information as far as where it is.
12 Also helping that restoration process because we
13 now can get our trouble men and our crews to the
14 locations faster.

15 We also see something from our side
16 which is right now for single load lights. So in
17 other words a customer's breaker on their panel
18 has blown. Right now we send a trouble man out to
19 the household to take care of those problems to
20 ensure that indeed they have power to their
21 system. Well we envision that with AMI that we
22 will have that information readily available and
23 can tell them.

24 We also see that it provides opportunity
25 to identify issues with regards to how the system

1 is operating and what it's state is. And that
2 comes down to local loading. What can I push
3 harder. Optimizing utilization of assets. And
4 just better levels of information for our overall
5 system, system design and optimization.

6 And just looking at given, we give you a
7 price signal. What would that response be and how
8 does that change how we plan and a design system.
9 So those are a few things.

10 MR. DOW: Luther Dow. Very similar
11 comments. Maybe saying it in a slightly different
12 way but I think similar to the same themes.

13 First of all I'm not sure whether
14 there's a full agreement on how the system works.
15 What is the system? We have a vision of what it
16 might look like but we're not sure how it works.
17 Are we going to -- Is the utility going to control
18 the load or are we going to provide price signals
19 to the customer so they can control the load?

20 Those are two different approaches, they
21 end up with two different -- you end up with two
22 different solutions depending on how that works.
23 So I think there's still a lot of understanding
24 that needs to take place there.

25 I wrote down interactivity between the

1 utility and the customer. How do we make full use
2 of these low carbon resources when they're
3 available? So there needs to be, there needs to
4 be some interconnectivity or interaction between
5 the utility and the customer. I call it a
6 partnership and that's what I think the future
7 looks like is a partnership between the utility
8 and customer.

9 I'm sure the system is going to have to
10 be modeled differently when we have all of these
11 devices on the distribution system and we don't
12 have those modeled in there today. So we're going
13 to ultimately have to do that, look at it
14 differently.

15 And the one thing that we're really
16 looking for and trying to make sure that we have
17 is we need to have early successes. We need to
18 have -- The first prototypes and the first
19 projects need to be successes so that we don't, so
20 that we don't fall backwards and we can build on
21 those successes as we go forward.

22 And then the last piece, of course, is
23 the cost of doing this.

24 And I agree with what has been said
25 about AMI. My comment about how will it be used

1 and it's going to provide better support to the
2 customer. It's going to really be useful to the
3 customer. And also useful to the distribution
4 system in the fact that we'll be able to monitor
5 loads better, we'll be able to respond better and
6 we'll be able to do load management better and the
7 system will run more cost effectively.

8 ASSOCIATE MEMBER GEESMAN: Do you think
9 that the roll out of AMI will facilitate a greater
10 ability on the part of regulators to bring rates
11 and costs into closer alignment? Particularly
12 time of use costs.

13 MR. DOW: Yes.

14 ASSOCIATE MEMBER GEESMAN: What is going
15 to happen when my neighbors in a pretty low air
16 conditioning area discover how much we are
17 subsidizing, cross-subsidizing new air
18 conditioning in the Central Valley? And I suggest
19 to you that each of your service territories are
20 likely to find the same geographical discovery on
21 the part of coastal residents.

22 Won't AMI potentially be one of the most
23 disruptive technologies ever introduced onto your
24 system? I think there's very clearly that
25 potential because we have allowed our rates and

1 costs to fall so totally out of alignment with
2 each other.

3 And don't get me wrong, we're strongly
4 supportive of AMI at this Commission. But I think
5 we are also just as supportive of trying to limit
6 cross-subsidies and align costs with rates.

7 MS. KELLY: Russ.

8 MR. NEAL: Well, this is Russ Neal with
9 Southern California Edison. The opinions are my
10 own here, not those of my employer necessarily.

11 But as I just read the words here and it
12 says, what is the most significant barrier to
13 creating a modern 21st century low carbon energy
14 network. I mean, my honest answer to that would
15 be the state's current aversion to considering
16 nuclear as an option.

17 What got me thinking along these lines,
18 in order to shift a little blame here, it was some
19 of the work that came out of Eric's shop in DOE
20 recently about the use of plug-in hybrid electric
21 vehicles as a load leveler for the system. One of
22 the salient features of our electric system is the
23 load factor. The fact that we have this enormous
24 capital infrastructure which gets very low
25 utilization sometime and is strained right at the

1 peak at the other time is one of the most
2 uneconomic features of our current electric
3 system.

4 And when one considers Eric's study, the
5 DOE report that came out and said how plug-in
6 hybrid electric vehicles could be integrated with
7 the system through the AMI which allows now, that
8 would allow this communication now for optimal
9 charging, and in fact even using the battery
10 storage of the vehicles as a resource for the grid
11 as well as the grid a resource for the vehicles,
12 is a very, very attractive avenue to explore.

13 And if then the baseload, if then you're
14 moving all of your generation into almost a
15 baseload mode the case for either things like
16 nuclear or a coal system with carbon sequestration
17 that is providing an economic baseload, low
18 emission situation. And you're also moving a lot
19 of the vehicle emissions out of the picture at
20 that point. Is to me an extremely scenario that
21 is not getting the consideration its due.

22 MS. KELLY: Let me just --

23 ASSOCIATE MEMBER GEESMAN: I think it's
24 getting more consideration than you might think,
25 Russ.

1 MS. KELLY: Just let me add one thing.
2 When I gave Russ's references I did leave out this
3 one part because I didn't think they were
4 relevant. He's a registered professional in both
5 electrical and nuclear engineering and his
6 previous experience includes five years as an
7 officer in the Surface Nuclear Navy. So now
8 relevant to your comments.

9 We need to keep going but do you have
10 one last comment, John?

11 MR. WESTERMAN: Yes, there's a couple of
12 things. One is, one of the things talking about
13 the new technologies. I think that one of the
14 premises of the Smart Grid is that it's not fully
15 dependant on the development of new technologies.

16 It's dependant on changing the way
17 things are operated and how data is collected and
18 how things are controlled. So if there was no new
19 technology development, the new technology helps
20 facilitate it but it is not required to start
21 going down that path.

22 And the other thing is I think there's
23 a, it's not a barrier but I think there's a missed
24 opportunity because I don't think that there's a
25 -- I'm one of the only non-utility people sitting

1 here so don't take it in a negative manner.

2 But I think customers are out there
3 doing things to try to improve their businesses
4 and reduce their energy costs. And the utilities
5 have programs to do similar things for the
6 customers but they're not, there is not a
7 partnership. There is not really a partnership
8 and I don't think there is really a mechanism at
9 this point for the utility to go out and be able
10 to say, we'll help you solve your problem and in
11 the meantime with the resources that get
12 implemented we can help you as a resource for
13 solving some of our problems.

14 And I think there is a large
15 opportunity, specifically as an example like DG.
16 A good DG opportunity is a college campus or a
17 hospital but they're not necessarily always
18 located on the feeder that has some requirements
19 for additional resources on it. So the utility
20 can target something like that to provide that
21 information to some of the end users there is
22 some, you know, further optimization that can be
23 made for the whole network.

24 MS. KELLY: Thank you. We have blue
25 cards.

1 PRESIDING MEMBER PFANNENSTIEL: I'm
2 sorry, did you have a question, Tim.

3 ADVISOR TUTT: I do have a question and
4 it relates to the concept of a partnership with
5 customers and the customers being able to sell
6 energy or provide energy to their neighbors. Is
7 net metering currently a barrier to such a future
8 and what would you do about that?

9 MR. DOW: I don't know if we'd say net
10 metering is necessarily a barrier but I think
11 there certainly is, there is a regulatory change
12 that would probably have to take place to allow
13 that to happen.

14 PRESIDING MEMBER PFANNENSTIEL: Linda,
15 have you finished your questions to the panel?

16 MS. KELLY: Yes, that's the end of the
17 questions. Now the blue cards and --

18 PRESIDING MEMBER PFANNENSTIEL: We do
19 have one blue card. Nora Sheriff would like to
20 comment on the panel.

21 MS. SHERIFF: Thank you and good
22 morning. Nora Sheriff for CAC and EPUC in terms
23 of the distribution system planning and building
24 the distribution system to meet the California
25 energy goals. And my question is really directed

1 towards PG&E and Edison.

2 I understood Edison to say that there's
3 no anticipated problem in terms of integrating the
4 million solar roofs from the California Solar
5 Initiative program. And I'm just wondering, what
6 about integration of the Energy Commission's goals
7 for combined heat and power into the distribution
8 system when you do your plan for the distribution
9 system upgrade and looking at what the goals are.

10 MR. NEAL: That's a little more
11 complicated. The reason I said there was not much
12 of a problem for the solar roofs is that they tend
13 to be a large number of small generators being
14 connected relative to the feeder they're connected
15 to. In that sense they're managed much the way
16 new load is managed, it's a statistical issue. I
17 don't worry about the fact hat a particular solar
18 panel might go off-line at a time when I was
19 counting on it.

20 But if I have -- The most economic
21 combined heat and power units are larger. They're
22 close to the size of the full capacity. Let's say
23 I have a ten megawatt feeder with a five megawatt
24 combined heat and power unit connected to it. I
25 have to be very concerned about whether that unit

1 will be generating the power at the time of the
2 peak when I need it or not or whether I have any
3 control over that fact or not.

4 So it becomes, each of those kind of
5 become a case by case engineering study to do. I
6 can't just treat that, you know, statistically
7 when I'm dealing with a sample space of one. So
8 it is more, there are more issues involved if one
9 wishes to integrate a combined heat and power.

10 Also the combined heat and powers tend
11 to be rotating machines which contribute to short
12 circuit duty and have some other potential impacts
13 on the system that the inverter connected systems
14 do not have.

15 MS. KELLY: And PG&E?

16 MR. DOW: The issue, it's a matter of
17 size. So it's a matter of impact from a system.
18 The combined is very big and so you have to pay,
19 you have to do a bigger study. When you do the
20 solar panels they're localized. You may have more
21 problems because you have more of them but they're
22 smaller and they're localized.

23 MS. SHERIFF: And then could I ask a
24 quick follow-up question, if I may? In terms of
25 your planning of what you're going to do over the

1 next year or the next five years or the next ten
2 years. Is there a correspondence between what the
3 utility has planned in terms of its procurement
4 with its distribution system planning, maintenance
5 and upgrade?

6 MR. NEAL: Are you referring to energy
7 procurement or to hardware procurement?

8 MS. SHERIFF: I'm referring to energy
9 procurement. The utilities' testimony in the
10 long-term procurement plan proceeding and the
11 forecast of, you know, 25 megawatts a year of
12 combined heat and power for Edison over the next
13 ten years of new CHP being added. And then for
14 PG&E 28 megawatts of new CHP being added.

15 Is there, is there a congruence there
16 between that procurement forecast and what the
17 distribution system planning is?

18 MR. NEAL: You know, I think those
19 levels -- And I wasn't involved and I am not an
20 authority on the procurement side of it but, you
21 know, that type of a forecast being spread over
22 our system is something that we would be handling
23 probably the same way we have been handling it up
24 to now. These are ad hoc projects, we just
25 engineer each one. It's well within our

1 capability to manage, manage those.

2 It's getting to the point, you know.

3 Getting to the place where solar panels are plug
4 and play is one thing. Wanting to get CHP to a
5 place where it's plug and play is quite another.

6 MR. DOW: And I don't know the answer to
7 your question.

8 MS. SHERIFF: Thank you.

9 PRESIDING MEMBER PFANNENSTIEL: Thank
10 you. We do have one other commentor on this
11 panel. M. L. Chan from KEMA.

12 MS. KELLY: Mr. Chan has a very short
13 presentation.

14 DR. CHAN: Thanks for giving me the
15 opportunity to share with you. It's almost kind
16 of like a summary. I think we're talking about
17 distribution system infrastructure. And I think
18 basically I just want to kind of, in a certain
19 sense, maybe put a little bit more of my spin on
20 the things being talked about this whole morning.

21 I do believe that this could be driven a
22 lot by the DGs, and particularly I think DG with
23 storage, not DG on its own. And I think on
24 renewables, they're going to form microgrids. And
25 then we talk about the hybrid EVs and so on. It's

1 going to call for an interface with some kind of
2 home automation system too to do load leveling as
3 Russ was talking about.

4 PQ is a concern. Service reliability is
5 definitely a concern. Sustainability and global
6 warming is driving a lot of these things, DGs and
7 renewables and so on and hybrid EVs.

8 But I think that personally I just want
9 to introduce something that I personally feel that
10 you need to look at it from an elemental analysis
11 when you look at sustainability and global
12 warming. Because you may be looking at
13 suppressing -- from an energy efficient viewpoint
14 how much it takes from the chemical element into
15 the end use.

16 That's how you want to analyze
17 efficiency. Not just to focus on the particular
18 aspect because it may take a lot more energy to
19 really come up with something. Maybe a compact
20 fluorescent light bulb, for instance, than maybe
21 putting just a generating plant out there. So you
22 need to look at the whole thing together. That's
23 what I call elemental analysis.

24 And then of course, I mean, there's also
25 the driver for efficiency. So this is just kind

1 of a picture of what you see in the grid. You
2 have the dispersed generation throughout. But I
3 think that results in the requirements that you
4 won't have more visibility to the distribution
5 system. That's why we talk about all these
6 sensors and so on.

7 In particular on the distribution system
8 I would like to encourage looking into what are
9 called inexpensive PMUs, which is already used for
10 transmission. So then look at some inexpensive
11 PMUs to get a good visibility of what is happening
12 in the system.

13 And I can see maybe down the road that
14 state estimators will be something that is needed
15 for the distribution system.

16 More local intelligence control because
17 I think right now basically we need to have a lot
18 of, putting a lot of burden on the communications
19 infrastructure just to do all this. Somebody was
20 saying, yeah, it's an IT system, bring all the
21 information back. But you want to put as much
22 local intelligence as possible so that you don't
23 have to depend on the pipe. If the pipe breaks
24 then everything falls apart. So you want to have
25 the local intelligence to be able to do that.

1 The Peer-to-peer kind of communication
2 is important. And I think we talked about
3 interoperability. It's also important to talk to
4 all the devices.

5 And then I think the system has to be
6 more hardened because we are talking about
7 infrastructure, not just talking about an
8 information system. So that's important. We've
9 got to figure out -- we're looking at underground,
10 composite material poles. Like what the Avanti
11 kind of a circuit is demonstrating too. Maybe
12 shorter response time with mobile data terminals.

13 And then I think the particular system
14 is a two-way power flow. So something that puts a
15 lot of burden into it. So how do you design your
16 system protection. Because the relays you used to
17 look at it in one-way. The power flow now, you're
18 looking at a two-way direction so the whole thing
19 needs to be reexamined.

20 So definitely condition-based
21 maintenance and then we can talk about this whole
22 differentiated reliability for different grids.
23 Because when you're talking about microgrids,
24 community development, it may be a cause of a
25 different kind of reliability standard for that

1 area versus a postage stamp type.

2 So that's why I think enabling
3 technologies make this whole thing happen. There
4 will be sensors, we can talk about communication
5 infrastructure, enterprise IT system and holistic
6 approach in the corporate culture.

7 And that leaves us the whole Smart Grid.
8 AMR is the first level, AMI is the next level, and
9 then the third level is where you do all the grid
10 control and load management.

11 And that really is sort of a picture of
12 what you will see. The sensors and the fuses.
13 Going for the communications infrastructure and
14 then the company is the enterprise information
15 integration to utilize the information. So those
16 three are really the basic building blocks for you
17 to implement this new distribution infrastructure
18 in the future. And then placed in there is the
19 whole corporate culture of holistic.

20 So I just want to maybe say one comment
21 about the bandwidth requirements. As you talk
22 about AMR, yeah, I think it's a smaller pipe kind
23 of application. But if you move up to AMI and
24 into these grid applications you're calling for a
25 larger and larger pipe. So that is really one of

1 the major enabling technologies. Once you put a
2 system in place that's this bandwidth then you can
3 accommodate and make things happen. This part is
4 not important given time.

5 But I just want to share the last slide
6 with you. Kind of like what we call a mid-20th
7 century grid. I think it actually came from the
8 Global Environmental Fund. A lot of people, we
9 see money is being spent on these energy-kind of
10 ventures.

11 So basically what we're saying is say
12 for instance there is some electromechanical kind
13 of system, now we'll looking at a digital system.
14 The one-way communication will expand more to a
15 two-way communicating system. It's built for
16 centralized generation now but in the future it
17 will be all the DGs and renewables, support EVs
18 and hybrids and so on. The load is moving around
19 incidentally with the EVs. It's not a fixed load
20 as before too, they move around.

21 The radial topology right now to more of
22 a network, bidirectional power flow so it's very
23 different. Right now it's all manual, it's going
24 to be all automatic, semi-automated and decision-
25 supported systems also. Eventually even self-

1 healing.

2 I think maybe just sort of the last
3 times there. The limited price information to a
4 full price information system down the road that
5 the people will be responding. The customers and
6 the utilities, they will be having this
7 partnership together and making it happen.

8 So this is, I think, in a certain sense
9 kind of pointing out where the research needs will
10 be done on the high level. But I think I just
11 want to kind of share that with you.

12 MS. KELLY: Questions?

13 ASSOCIATE MEMBER GEESMAN: How expensive
14 are you envisioning an inexpensive distribution
15 system PMU to be?

16 DR. CHAN: I think essentially those are
17 cheap phaser measurements. I have seen vendors
18 coming up with those. There is a vendor in
19 Florida exploring that. As a matter of fact, I
20 think Eric is here and then Russ. There is a
21 project ongoing, an advanced feeder automation
22 project. DOE is funding that and it's done over,
23 going to be done at the Avanti Circuit Future.
24 And actually I think PG&E is also partnership to
25 that one too. Indeed we're exploring that.

1 I mean, they are, they are not the
2 multi-hundred thousands, those kind of values.
3 But the cost is still, maybe it's an older
4 magnitude. Definitely lower than that one.

5 ASSOCIATE MEMBER GEESMAN: Thank you.

6 PRESIDING MEMBER PFANNENSTIEL: Thank
7 you.

8 MS. KELLY: On the telephone are there
9 any questions? Any final questions before we
10 close for the morning?

11 UNIDENTIFIED TELEPHONE SPEAKER: No,
12 thank you.

13 MS. KELLY: Thank you. Okay. Chairman
14 Pfannenstiel.

15 PRESIDING MEMBER PFANNENSTIEL: Why
16 don't we come back in one hour. So make it, make
17 it an hour and five minutes so it will be 1:15.

18 MS. KELLY: Thank you.

19 (Whereupon, the lunch recess
20 was taken.)

21 --oOo--
22
23
24
25

1 AFTERNOON SESSION

2 PRESIDING MEMBER PFANNENSTIEL: I think
3 we'll start the afternoon session. We have a long
4 afternoon ahead of us with a lot of good
5 information. Commissioner Geesman will join us in
6 a couple of minutes.

7 I did want to introduce Commissioner
8 Byron who was not able to be here this morning.
9 He was at a successful quest at the Senate Rules
10 Committee. He has been approved by Senate Rules
11 Committee and so welcome, Commissioner Byron.

12 ASSOCIATE MEMBER BYRON: Thank you,
13 thank you Madam Chairman. Yes, I'll be around for
14 another three and a half years or so. Thank you
15 very much.

16 And if you don't mind I would like to
17 acknowledge someone very important to me. It's
18 kind of rare that she's here today but my wife was
19 here supporting me and there she is. Debbie,
20 would you just wave. Debbie. It's so rare that
21 we get a spouse in here Debbie so thank you for
22 coming. And if I don't --

23 (Applause).

24 PRESIDING MEMBER PFANNENSTIEL: Clearly
25 the key to your success, Jeff.

1 ASSOCIATE MEMBER BYRON: Yes. I'll see
2 you later.

3 PRESIDING MEMBER PFANNENSTIEL: Okay,
4 full agenda. I'll turn it over to Linda.

5 MS. KELLY: Okay. Thank you everybody
6 for returning. We do have a full agenda so why
7 don't I go ahead and just start.

8 I am going to talk to you this afternoon
9 -- well, just let me summarize. Basically this
10 afternoon we're going to focus on research
11 programs, challenges and opportunities to address
12 distribution issues that we really identified
13 during the morning.

14 I want to start with a brief discussion
15 and an overview of the PIER program that I work
16 for in the distribution area.

17 Jose Palomo will also give you an
18 overview of the Distributed Energy Resource
19 Integration Program and then Rachel MacDonald will
20 finish with an overview of the new cross-cutting
21 microgrid project that we're going to be jointly
22 pursuing in the next few months.

23 The PIER Program is actively funding now
24 nearly \$400 million in research. It is a leader
25 in low carbon technology and climate change

1 response. We have a very active global climate
2 change program. We address electricity, natural
3 gas and transportation issues. Currently there's
4 around \$80 million in our annual budget and nearly
5 \$400 million in active projects.

6 We are divided into various focus areas
7 that look at research from different perspectives.
8 We have an efficiency and a demand response
9 research program that looks at building
10 efficiencies, industrial ag and waste
11 efficiencies. Our demand response program has
12 been very active in developing price responsive,
13 demand response technologies and supporting those
14 programs.

15 We have a renewables program. We have
16 clean fossil fuel generation that is referred to
17 as the Environmentally Preferred Advanced
18 Generation program. The Distributed Generation
19 program that I mentioned that Jose is the program
20 manager for. We do combined heat and power.

21 We are now very much involved in
22 transportation. We are developing a brand new
23 transportation program that we expect to really
24 make a difference here in California.

25 Energy Systems Integration is the group

1 that I belong to. Transmission and distribution
2 are in that area. This says grid interconnection
3 but that's work that Jose Palomo does with his
4 Distribution Integration Program.

5 We also have a security program. It's
6 not here on that slide but I did want to mention
7 that. Our environmental program looks at air,
8 water, climate and communities and is very active
9 in supporting California policy.

10 Thank you. I'll get these lights right
11 yet. I thought that what I'd like to do is --

12 Because I am the program manager of the
13 Distribution Research Program and one of our
14 primary research objectives is to focus on
15 supporting the development of low carbon energy
16 networks. I thought I would start my presentation
17 today by explaining what a low carbon energy
18 network would look like and why this vision of the
19 future delivery system supports California policy
20 objectives and I think really should be a high
21 priority.

22 I don't think that all Smart Grids are
23 low carbon energy grids. I think California has a
24 unique perspective and we have made a strong
25 commitment to low carbon reduction. So I think

1 that this vision and this grid that we're looking
2 at will help us get to that specific objective,
3 besides some of the Smart Grid objectives.

4 I tried to explain this to my husband
5 and he said, I don't understand this, so I thought
6 what I'd do is just tell you what it would it
7 would look like. It would have new interfaces and
8 standards and regulations that would allow for the
9 free exchange of energy services between the
10 utility and its customers and make customer
11 adoption of advanced technologies simple and
12 understandable. No small challenge.

13 Distribution system design. We're
14 looking at both the customer and the
15 infrastructure in this vision. Distribution
16 system design accommodates high penetrations of
17 low carbon customer technologies. This is where
18 you get into the efficiency, demand response,
19 renewables, CHP, storage. Microgrids will be part
20 of this vision and the plug-in electric hybrid
21 vehicles.

22 And it's important that the grid be able
23 to utilize these resources to improve its
24 reliability and efficiency. They need to become,
25 these resources need to become more than

1 megawatts. Sorry Russ but I think that's the way
2 it needs to be in the future.

3 Also this low carbon network will really
4 need to integrate advanced technologies. And
5 we'll hear about a lot of those today but these
6 are really critical. Advanced sensors,
7 automation, power electronics, communications and
8 planning models that will help optimize the
9 network in real-time, like the transmission
10 system. The benefits would include increased
11 distribution energy and resource efficiency.

12 It is really important that as we move
13 to this type of a network that it be efficient. I
14 think we can move there, and if we don't take care
15 it will cost a lot of money. But I think if we do
16 it right it will give us a lot of benefits and
17 will actually be a low cost energy network.

18 And as Russ mentioned and all the people
19 from the utilities. Customers I think need to be
20 able to select their desired level of reliability
21 and utilities can provide it.

22 And this I think is a key characteristic
23 of what the low carbon energy network would like.

24 This slide is about technologies.
25 You've heard about some of them mentioned in

1 passing this morning as important and you'll hear
2 in detail this afternoon about why these
3 technologies are important and where they fit in.

4 I think it's important to understand
5 that if these technologies are not developed and
6 integrated to at least some extent into the new
7 system Californians will have to continue to rely
8 to a larger extent on central generation. I think
9 that reliability costs, and I think this was
10 confirmed today by presentation, you know, by
11 utility representatives.

12 Reliability costs and impacts can be
13 expected to grow as well. The amount of
14 infrastructure that we have built will probably be
15 suboptimal and increase costs as well. So we find
16 that developing this type of resource is really
17 consistent with our low carbon energy network
18 goal.

19 And the program right now, the
20 Distribution Program in the area of sensors, we
21 talked about sensors. We're going to be working
22 with developing a project now that we're hoping to
23 get approved very shortly that will look at
24 underground cables. This will be a unique
25 opportunity. We have some very good professors

1 who have very unique I think skills across
2 industries to ask the right questions and to begin
3 to discuss what are some of the new solutions.

4 But as a commitment to that project --
5 Because this is a nationwide project, this is not
6 just -- Cables are not just a problem for
7 California, they're a problem for all distribution
8 utilities throughout the United States. As a
9 commitment to that as a part of that research we
10 are going to convene a large conference in which
11 we are going to bring experts from the private and
12 public industry to help us understand what the
13 issues are help these professors find a solution
14 that I think that everybody is looking for.

15 We are also looking at low fault
16 detection with these sensors. This is a small
17 project that we have going that says, can very
18 cheap, tiny sensors detect faults at the
19 distribution level. The question is, you know,
20 can you embed the sensors.

21 But then I think another critical issue
22 is, in the distribution environment will these
23 sensors work? A lot of these sensors are being
24 developed for homes now. The distribution system
25 is a much different environment.

1 We're developing information modeling
2 tools to help us understand where distributed
3 energy resources have value and we're also doing
4 some work looking at the financials with regard to
5 that.

6 We're doing our value of distribution
7 automation study and we expect to start research
8 in the next few months on areas that are
9 determined in that study.

10 We are also -- The key, big thing today
11 that we're going to talk to you about is
12 microgrids. We think microgrids are really
13 critical to understanding what the low carbon
14 energy network on a small scale can do first and
15 then expand it to the larger grid as well as
16 microgrids.

17 So we're going to need technology to
18 make power delivery systems smart. But the low
19 carbon energy network will not evolve without the
20 full integration and ability to utilize customer
21 resources that I think will be developing
22 increasingly in the next five to ten years.

23 Customers, I think, are -- as a customer
24 myself I know that a lot of these technologies can
25 be very daunting and perplexing. But I think that

1 we are all going to have to begin to think about
2 what our role will be as we go forward.

3 So the challenge is environmentally and
4 siting constraints -- environment and siting
5 constraints will make it, I think, increasingly
6 difficult to meet California's energy needs with
7 the traditional central station generation and
8 transmission. I think this is supported by policy
9 as well, even if those were not issues I think our
10 policy is moving to a more distributed system.

11 The solution. Decentralized energy
12 resources could be called upon to meet a larger
13 share of these capacity and energy needs. To
14 ensure that these distributed resources are
15 available owners and customers need to understand
16 how to participate and have sufficient incentives
17 to do so. To gain the maximum leverage and
18 benefits from these resources the distribution
19 system must be optimized to provide transparency
20 and operating flexibility for these grid
21 operators.

22 I guess it was on the 7th we had a DG
23 workshop and Commissioner Byron asked the question
24 about choice. And he asked Jane Turnbull, who is
25 still in the audience today. And he said, do

1 customers want choice. And she said that she
2 surveyed her members of the League of Women Voters
3 and 80 percent of them didn't.

4 And that doesn't surprise me but I think
5 it gives us another issue to work on. Because I
6 think it's important that these customers -- and I
7 am probably one of them. I am not really anxious
8 to do a lot of the things that Russ says I don't
9 want to do, he's probably right. But if we
10 develop the right technology, smart appliances,
11 easy interfaces, I certainly am expecting that I
12 would be willing to do this if I was given the
13 right incentives, if I understood the programs and
14 I had the technology to support those decisions.

15 I do think customers, and even
16 residential customers, are going to need to be
17 part of the low carbon energy network.

18 MS. TURNBULL: May I respond?

19 I am Jane Turnbull of the League of
20 Women Voters. I do want to note that in fact our
21 customers do like the idea of dynamic rates. They
22 want to make choices in terms of their own
23 personal options and use of energy. They don't
24 want some individuals to be able to have a
25 different set of rates. If it is going to be real

1 time it should be real time for everybody.

2 MS. KELLY: No, I agree. Again, I think
3 the programs are going to have to be transparent
4 and everybody is going to have to understand them
5 and they're going to have to be fair and
6 equitable, certainly yes. It's all part of the
7 challenge in figuring it out.

8 Let's see, okay. I lost where I am,
9 sorry. Okay. So now that you have a better idea
10 of what a low carbon energy network would look
11 like and some of the technical issues and
12 challenges that have been addressed.

13 I think I'd like to quickly review the
14 areas that the distribution program is working on.
15 I think that the areas that we are working on are
16 consistent with some of the issues that were
17 raised and I think this research will be helpful
18 in addressing some of those issues. How we
19 develop these initiatives and what technologies we
20 develop I think in some cases is still to be
21 better understood but I think we're on the right
22 track.

23 Integration of DER and demand response.
24 I think that we have a research project in which
25 we are looking at developing modeling tools that

1 will improve the visibility. There's a number of
2 them around now but we want to improve the
3 visibility in the distribution system.

4 As I mentioned, we are working with DOE
5 to look at business case development with actually
6 Southern California Edison. Let's look at from
7 the financial perspective of the utility the cost
8 of their traditional capital investments. And
9 using the same financials let's take some DG, or
10 maybe it would be some demand response, and let's
11 look and see how those compare to the traditional
12 utility resources.

13 In some generic cases already, we did
14 some initial work, the time frames that they would
15 defer some of these resources that Russ mentioned
16 for seven to eight years potentially. I think we
17 are going to look at them again and reevaluate the
18 benefits in there and see, you know, if we can --
19 if those numbers can be improved. If they include
20 societal values. But we are definitely going to
21 pursue that some more.

22 Efficiency and DR. This is a project
23 that we did with the San Francisco Co-Op and we're
24 looking at diverse customers' opportunities to
25 provide a range of support services to a

1 particular circuit. And I think what we have to
2 do now that we have some of those initial results,
3 begin exploring how utilities can partner with
4 these customers to take advantage of these
5 resources.

6 Distribution automation. As I said,
7 distribution automation is something that we
8 found, we had a workshop, it is clear that
9 distribution automation helps utilities with
10 reliability now and it is clear that it will help
11 them in the future improve their reliability.

12 The challenge that we have in this
13 research project is trying to understand what
14 other benefits we can get from distribution
15 automation. Can it support the integration of DG?
16 These are some of the public interest areas that
17 we are interested in so we want to look, you know,
18 from a public interest point of view, can
19 automation provide other values beyond or building
20 upon the value of reliability to the utilities.

21 Energy storage is clearly very
22 important. We want to look at it at the
23 distribution level. We'd be very anxious to
24 include it if it was appropriate in our microgrid
25 project to see how storage can support a

1 distribution customer and activities and
2 communications. You know, I think today we'll
3 have a lot of briefings on how communication and
4 data technologies are going to be critical to the
5 interoperability of the system.

6 So beyond working with these core
7 technologies that is an overview of the
8 distribution program. What I wanted to do is to
9 talk today about a new approach that we are
10 taking. The distribution and distributed energy
11 resource integration programs are joining together
12 to do cross-cutting research projects and
13 coordinate program activities.

14 We do coordinate, we do collaborate, but
15 we're really focusing -- we think that the
16 distribution and the distributed energy resource
17 integration program, it's the connection between
18 the customer and the distribution system.

19 So these resources and the distribution
20 system are the core of a low carbon energy network
21 and so we have decided that we are each going to
22 pursue core technologies to make sure that in the
23 distribution area and the DG area core
24 technologies are still addressed. But we are
25 really going to look and see where we can find

1 cross-cutting projects that we can work on
2 together.

3 We share a common vision. We have
4 decided to do that, technologies that have been
5 developed and brought to market that provide
6 efficient, reliable and affordable energy to
7 customers through a low carbon energy network.
8 This is the vision that both our programs have.

9 We support -- Both programs support the
10 integration and efficient use of low carbon
11 customer resources, again CHP, microgrids, PV, et
12 cetera. Cross-cutting research addresses
13 milestones in both roadmaps. The work we are
14 doing in my program and Jose's program can be seen
15 on both our roadmaps. It supports both
16 distribution research and DG research.

17 And then I also want to build on the
18 collective experience of both programs. The DG
19 program is a mature program. It has a lot of
20 experience and it has developed a lot of very
21 useful research and made a lot of inroads at the
22 customer side for distributed energy resources.

23 The distribution program is new. We are
24 just beginning to try to try to make these
25 efficient connections. So Jose and I and Rachel,

1 and Bernard Treanton who is part of our team, have
2 decided to put our programs together and develop
3 cross-cutting research.

4 So the next person to speak is going to
5 be Jose Palomo. He is going to come up and he is
6 going to talk to you about the distribution energy
7 research integration program. And particularly he
8 is going to talk to you about some of the
9 microgrid work that he is doing.

10 And then he'll be followed by Rachel
11 MacDonald who works with me on the distribution
12 program and she is going to tell you some of the
13 details about the microgrid project that our two
14 programs are looking to develop in the spring of
15 next year.

16 Questions? No?

17 On the telephone are there any
18 questions? Okay.

19 MR. PALOMO: Thank you, Linda. Good
20 afternoon everyone, my name is Jose Palomo, I work
21 for the DER integration. I thank you for giving
22 me the opportunity to present some of the work
23 that we have been doing, some of the research
24 work.

25 I am going to be presenting -- thank

1 you. I am going to be presenting some of the work
2 that we have been doing in the microgrid research.
3 I'd like to introduce Bernard Treanton who has
4 been heading this project on the microgrids here
5 at the Commission for the last, for the last few
6 years.

7 My presentation is short, I have three
8 major items to present. Basically the DER
9 integration program overview followed by the
10 cooperative efforts that we have with the
11 distribution research program and then some brief
12 overview of the microgrids research that we are
13 going to cooperate on.

14 I'd like to provide a definition of my
15 program. basically this is basically what the
16 program focuses on, issues related to using
17 relatively small-scale DG as part of the larger
18 interconnected electricity grid. It's a simple
19 concept but basically it covers, it addresses the
20 electricity problems and addresses issues in the
21 grid in California.

22 Through our research we have come up
23 with what is something that we call platforms.
24 Here's four platforms that we have identified as a
25 part of our research and we invest PIER funds in

1 research projects that basically address those
2 platforms.

3 This morning Mr. Luther Dow pointed out
4 that there's still some research that needs to be
5 done in sensor technologies, power electronics,
6 adaptive/protective devices and fault
7 anticipation. So that basically corroborates our
8 approach, research approach. We have come up with
9 these, with these platforms on our own basically
10 in analyzing the problems with the grid within the
11 state and all the electricity problems.

12 So we have invested funds in grid
13 effects with the objective of understanding the
14 impact of DER on the grid and we have evaluated
15 some of the effects of anti-islanding and voltage
16 regulation and stability.

17 In addition we have been, we have funded
18 power electronics projects with the objective of
19 reducing the cost and improve the functionality of
20 DER. And we have been able to develop some
21 universal interconnection devices, modular highly-
22 integrated devices for various DER platforms.

23 Everybody hear me better now? In
24 addition we have invested funds in interconnection
25 by streamlining Rule 21 and we are also going to

1 be investing in advanced network protectors. And
2 we have monitored DG with the objective of
3 reducing the timing and costs for interconnecting
4 DER to the grid.

5 Finally, market mechanisms with the
6 objective of determining how rates and tariffs
7 affect the market for DER. We are in the middle
8 of assessing the impacts of AB 32 on combined heat
9 and power and we are going to identify incentives
10 for utilities to integrate DER.

11 The projects funded by DER integration
12 have cross-cutting applicability in other PIER
13 activities such as the distribution research
14 program. And we have identified these coordinate
15 research activities that provide solutions for
16 each of the programs. In this case we have
17 microgrids, regional demonstration optimization,
18 energy storage integration.

19 This graph provides a time line of the
20 investments that we have been making in
21 microgrids. The Energy Commission together with
22 the Department of Energy have been supporting
23 microgrids since the year 2000.

24 In the year 2004 the Energy Commission
25 awarded a contract to the Center for Electric

1 Reliability Technology Solutions that is headed by
2 Lawrence Berkeley National Lab. By the end of
3 this summer, this year, this project that started
4 in 2004 is going to be finishing collecting data
5 and we believe that we're up to the next step
6 towards another demonstration and closer to
7 possible commercialization of microgrids.

8 This next graph explains the operational
9 concept of a microgrid. Basically they're DG,
10 these are DG interconnected on a small grid and
11 they provide a seamless islanding and re-
12 connection. What that means is basically this
13 grid, if you will, is connected to the major
14 electric grid by this point of connection.

15 And in the case that there is a
16 disruption or the microgrid is intentionally
17 islanded this switch opens up and there is no
18 disruption in the voltage or the current within
19 the microgrid. So these sensitive loads continue
20 working without any disruption.

21 In addition there is peer-to-peer. It
22 offers peer-to-peer autonomous coordination among
23 the micro sources. Basically each one of the DGs
24 could augment each other's voltage and so on.

25 Another feature of this microgrid is it

1 offers and plug and play option, which basically
2 requires no custom engineering. What that means
3 is that the equipment can be connected to this
4 network and it identifies with its own network and
5 talks to the other components and basically they
6 can manage the load by themselves. So one of the
7 advances on this concept is the electronics, and
8 also the software that manages this grid.

9 This is the actual application of the
10 microgrid concept. It is being tested, this is a
11 test bed in Columbus, Ohio and it features three
12 small sources, each 100 kilowatts. The technology
13 allows implementation of storage although at this
14 test bed it is not, it is not being used. That's
15 for future research.

16 In addition there is no power that flows
17 onto the grid at this time but that is something
18 that we would like to evaluate in the future.

19 I'd like to explain what you're looking
20 at here. This shed basically is where these three
21 Tecogen engines that run on natural gas are housed
22 and they provide electricity to some of these
23 switches. These are switches. And these are
24 simulated load. What you see over here is the
25 simulated wiring that would be typical of a grid

1 or a small grid. The data is being collected by
2 simulating voltages and variations of current and
3 so on.

4 So the microgrid tests will be completed
5 by this summer in 2007. The test results will be
6 presented at an IEEE session. We will explore the
7 -- the microgrid will explore the options for
8 integrating a variety of customer-owned
9 generation. Future projects will address
10 technical issues related to exporting to the
11 electric grid.

12 Additionally our PIER investments are
13 being leveraged by the Department of Energy to
14 advance the commercialization of the CERTS
15 microgrid concepts. And the DER and the
16 distribution research programs are planning to
17 demonstrate these microgrids in California.

18 Before the next speaker comes up does
19 anybody have any questions?

20 MS. KELLY: Thank you. Does anybody
21 have any questions there?

22 MS. MacDONALD: Good afternoon,
23 everyone. For the sake of time I'll just pretty
24 much go through this as quickly as possible. My
25 name is Rachel MacDonald and I work with --

1 MS. KELLY: Speak up.

2 MS. MacDONALD: Speak up. I work with
3 Linda Kelly here at the PIER program in the
4 distribution area.

5 As Jose mentioned we have current
6 funding and research going in Columbus, Ohio.
7 We're looking to bring that microgrid research
8 here to California and that is what this is about.

9 At this time Navigant is interviewing
10 utilities, customers, manufacturers and looking at
11 various locations to put a microgrid application
12 here in California. All stakeholders are welcome
13 to contribute to this process and I'll provide
14 that contact information at the end of this short
15 presentation.

16 We are also part of this process looking
17 to clearly define what values, value propositions,
18 definitions and things that we're looking for to
19 include in this work. This work is scheduled for
20 completion this summer, June and July. End of
21 June, early July.

22 Part of this, there has been a lot of
23 discussion as to what a microgrid is. We just
24 have a general definition that we're working with
25 right now and that it is that it a group of

1 technologies, obviously containing a generation
2 source. They are interconnected and they can
3 either be run concurrently with the grid, they can
4 be islanded, they can be interconnected.

5 And we clearly know what we consider a
6 microgrid not to be and that would be, for
7 example, one single generation source serving one
8 load. Or a group of houses, for example, with PV
9 that are not connected in any way or have any form
10 of control or communications group, group-wise.

11 Further in this work we are looking at
12 what we are calling value propositions. They are
13 basically values that are not mutually exclusive
14 nor are they ranked in order. And they're going
15 to help determine what is going to be the most
16 optimal application for California. In this case
17 many of them are often linked. For example, you
18 would have reliability and power quality often
19 going hand in hand together.

20 As part of this demonstration here in
21 California we're looking for, obviously, this work
22 to meet all the value propositions, fit in the
23 criteria or the definition of what a microgrid is.
24 And that it that it would be interconnected,
25 serving multiple loads and have DER and other

1 technologies. And to have -- We want strong
2 customer involvement with the utility, with our
3 end-users and manufacturers as well as cost-share.
4 And the cleaner technology the better.

5 And we are looking to again have the
6 scoping study done this summer by Navigant. That
7 will be, again, June or July ETA of completion.
8 And then we'll be taking that information and
9 going forward with looking at a demonstration,
10 hopefully to begin this spring 2008.

11 And if anyone that's in here would like
12 to contact Navigant that may not have been
13 contacted already the contact information is here.
14 It will be Forrest Small or Stan Blazewicz of
15 Navigant Consulting.

16 Thank you. Are there any questions?

17 Any questions on the phone? Okay.

18 MS. KELLY: Thank you, Rachel.

19 ADVISOR TUTT: Rachel.

20 MS. KELLY: Steven Moss. I'm sorry.

21 ADVISOR TUTT: One question. I didn't
22 see storage mentioned in your list of items. Is
23 that somewhere in there?

24 MS. MacDONALD: We are considering
25 storage as part of the other technologies as well

1 as demand response. I actually have that in my
2 notes here but I was trying to get through
3 everything. But yes, that's the other
4 technologies including power electronics,
5 communications and controls. The more
6 technologies that a prime, optimal microgrid would
7 be to have here in California the better.

8 MS. KELLY: I'd like to introduce
9 Steven. Steven Moss has been involved in energy
10 policy issues for more than a decade and a half.
11 He served as an expert witness predominately on
12 behalf of farmers and in a large number of
13 proceedings in front of the CPUC and the
14 California Energy Commission as well.

15 Steven is a member of our Program
16 Advisory Committee for the distribution program
17 and Steven is going to talk today about the
18 customer perspective. And I asked him to come and
19 speak about this because during the course of our
20 PAC meeting and what you heard this morning Luther
21 was -- I remember hearing Luther -- Luther just
22 keeps worrying about all these customer generation
23 resources are coming, how are we going to manage
24 them and what we are going to do with them.

25 And then on the other side Steven as a

1 customer representative was concerned about as a
2 customer I'm going to have this PV, this demand
3 response, this AMI. What am I going to do with
4 all this stuff?

5 So Steven today is going to talk about
6 some of his ideas about as more and more customers
7 begin to have these generation sources at their
8 homes some of the ideas they might have to think
9 for managing them. Steven.

10 MR. MOSS: Thank you, Linda and thank
11 you, Commissioners. So yeah, I'm Steven Moss and
12 I work with San Francisco Community Power as well
13 as with an economic consulting firm.

14 And as opposed to going through specific
15 research findings that we've had over the course
16 of the years or working with PIER I thought I'd
17 lift my head up from my computer and talk more, a
18 little bit more conceptually from a customer
19 perspective. And the customers I work with are
20 farmers, families and small businesses. So not
21 large businesses. It's a particular niche of
22 customers.

23 That said, the research we have done for
24 PIER to date has been provided as part of this
25 workshop in the form of a paper that is going to

1 be delivered at the ACEEE conference in July. And
2 that research continues and I'm happy to answer
3 questions about it.

4 As Linda mentioned, Luther has sort of said
5 repeatedly in the workshops I've been in with him
6 that it's important to look at the evolving
7 relationship between utilities and customers. And
8 he's using the word partnership, which I think is
9 an apt word.

10 I wanted to do a little conceptual
11 exercise around the term, duty to serve, duty to
12 serve. A key underpinning of monopoly utility
13 regulation is duty to serve. And the concept has
14 been part of the regulatory process for decades
15 and it has led to a variety of regulatory
16 implications.

17 As the concept sounds, the round idea is
18 that the monopoly of the utilities have an
19 obligation to provide service to just about
20 everyone no matter where they are, no matter who
21 they are, no matter how much it costs to serve
22 them. And as I say, this has shaped the utility
23 industry pretty significantly.

24 It has certainly made it more expensive
25 and more expansive than it would have otherwise

1 been without a duty to serve model and its nose
2 can be seen poking out of lots of different
3 regulatory policies from providing low-income
4 families rate discounts under the CARE program to
5 placing a higher value on transmission and
6 generation than one might actually think is
7 worthwhile from a purely economic perspective.

8 On the other hand it has worked. We
9 have equity in California and throughout the
10 United States. Almost everybody has access to a
11 utility system, to electricity provided by a
12 utility.

13 Now over time the idea of duty to serve
14 has shifted in sometimes subtle ways. Right now
15 there is less of an emphasis on access and more of
16 an emphasis on paying for what you get. And you
17 can look at time of use rates and critical peak
18 pricing as two illustrations of this new
19 relationship between the utility and the people
20 they serve. A different kind of duty. You don't
21 just get what you want at whatever price you want
22 it at. You may actually have an obligation to pay
23 a different kind of price.

24 And a case could be made, and I'm not
25 trying to make this case particularly strongly

1 today. I think it's more of an interesting
2 thought exercise and it bleeds into what research
3 is important in the state of California and
4 throughout the country. It could be that there is
5 a more revolutionary change going on with the duty
6 to serve concept.

7 Which is that over the next decade, or
8 maybe a little longer or maybe a little shorter,
9 that the duty to serve concept is going to be re-
10 balanced. It's going to be re-balanced away from
11 the utility and to the customer. Let me talk
12 about that and why that is important.

13 A couple evidence of that is things
14 like, again, time of use pricing or critical peak
15 pricing. Demand response programs are another
16 evidence of this. And under demand programs, as
17 you know, a customer, willingly in this case, may
18 be asked to give up megawatts kind of like a tiny,
19 little utility. In some cases maybe even a, you
20 know, moderate-sized utility.

21 Net metering on PV systems along with
22 mandatory time of use rates is another concept of
23 customer duty to serve. And the idea that we are
24 going to have smart meters in every home and
25 business takes it home essentially.

1 And the other concept that has been
2 floating around today, which has been talked about
3 now for awhile courtesy of the Department of
4 Energy is the idea that we're going to have
5 electric utilities breathing in and out of -- I'm
6 sorry, electric vehicles -- breathing in and out
7 of the electric utility system. Well now we've
8 really got an integrated system or some kind of
9 system in which duty to serve is all over the
10 place.

11 So in the future that seems to be
12 already unfolding rate payers don't look so much
13 like passive consumers of electricity in the, you
14 know, lights-on, lights-off kind of way but they
15 are a two-part of the grid. And that means they
16 have responsibilities and obligations that go
17 beyond just paying their bill.

18 And the question is, what does a world
19 in which consumers have a duty to serve look like?
20 One thing is, and I don't really know this for a
21 fact but I assume everybody around the table here
22 is an engineer. And you can raise your hand if
23 you're not an engineer.

24 It seems to me, and nothing against
25 engineers, but it seems to me that in this kind of

1 different relationship that the utilities look
2 different than a corps of engineers-type
3 structure, right. Historically a corps of
4 engineers, they go out and build stuff, hopefully
5 doing a good job of it.

6 And they look a little bit more, and I
7 look around and I don't know that this is exactly
8 an apt analogy, but a little bit more like
9 orchestra leaders. Where they are asking for a
10 different demand from here, maybe a tiny bit of
11 resource over there and they have electric
12 vehicles humming over there. So that they are
13 more coordinating a wider set of perhaps smaller,
14 diverse resources. I think it's already happening
15 even in an engineering kind of construct.

16 So this again is the thought concepts.
17 So the next step is, what models do we have in the
18 world today that would tell us how this new
19 system, if it does emerge in the utility system,
20 is going to look like. And you can think about
21 it. I mean, regional transportation systems come
22 to mind. These are locked in an engineering
23 approach. We build roads. But over time and
24 increasingly there are options, right, whether
25 it's mass transit or fixed rail or bicycle-

1 friendly or pedestrian-friendly places.

2 And then the evolution very much like we
3 are today with utilities, carpool lanes,
4 congestion pricing. You know, systems that try to
5 encourage a different sort of behavior in which
6 there is a relationship between the driver and the
7 road, really.

8 The health care system might also be an
9 example of this, at least the best qualities of a
10 health care system in which the patient is a
11 partner with the doctor. But I don't want to take
12 that too far.

13 The living, breathing example of this
14 kind of relationship I think right now are water
15 districts and irrigation districts in the state of
16 California. And I don't know if you're familiar
17 with these things but they're sort of quasi-public
18 collections of farmers who agree to take care of
19 shared resources, it started with water, now it's
20 increasingly energy that could be their commodity,
21 in ways that enhance the benefit of everybody in
22 the district.

23 So water utilities. Members of an
24 irrigation district are very familiar with being
25 told to stop using water at a particular time, or

1 being scheduled to use water at a particular time
2 and have developed the means to be able to deal
3 with that. Now water is not electricity. Water
4 is kind of oddly like electricity in that it can't
5 be stored, so to speak, but it can be stored,
6 right, by reservoirs and conveyances, but it's a
7 little bit of an odd commodity.

8 The energy systems in irrigation
9 districts I think they merit examination. They
10 are increasingly made up of -- I don't know
11 exactly what a Smart Grid looks like in the future
12 but what it looks like today in an irrigation
13 district is, you know, they have a PV facility
14 here, they have a natural gas-fired thing over
15 there. They have a diesel engine that hopefully
16 they're getting rid of next year. They're
17 connected to the utility system. They're
18 participating in some kind of critical peak
19 program. Maybe they even own some hydropower
20 somewhere. They have got a diversity of resources
21 which is being shared collectively among the
22 members of this irrigation district. So that's a
23 model I think may look like what we're heading
24 towards.

25 Now I'm moving towards, okay, so what

1 does this really mean to the utilities and I'm
2 just going to throw out three possibilities. One
3 is, you know, we have to plan the utility system
4 potentially differently.

5 And I'm very sensitive to saying
6 planning and utilities because I know utilities
7 are very sensitive about their planning processes
8 and have a good grip on them and I'm not wanting
9 to get into their face about how they plan, simply
10 point that there may be implications to planning.
11 Better ways of communicating and more
12 opportunities to participate by customers.

13 And once could make the argument that
14 the utility model as it is currently constructed
15 really is no longer apt for the future. That may
16 be going back to the past where PG&E was a bunch
17 of different tiny utilities, or something like
18 that is really a more apt model.

19 Tom was talking about value of service
20 and that they had discovered in San Diego that
21 there are differences in people's value of
22 services or provision of outages actually. But
23 while there are differences in the frequency of
24 outages and also in people's value of outages,
25 this actually has been known by farmers for a long

1 time. It's not a shock.

2 In the 1993 general rate case which I
3 participated in with PG&E the farmer group I
4 worked for proposed that agricultural rates be
5 modified based on their value of service, which
6 was rejected and has been actually proposed in
7 general rate cases since and always been rejected
8 for various reasons.

9 In the neighborhood I live in in San
10 Francisco I did a, we collected some outage data.
11 My neighborhood has higher outage rates than -- I
12 live in Potrero, which is near the ballpark. We
13 have a higher outage rate than say, Pacific
14 Heights, which is near the Golden Gate Bridge.

15 You can find geographic differences. I
16 actually was trying to find differences in low-
17 income versus high-income outage rates, it's not
18 there, at least in PG&E service territory so I was
19 happy to see that. But there are these
20 differences in outage rates that could be
21 geographic.

22 The idea that you might have area rates,
23 which has been floated again for several decades
24 and always tossed out for, again, actually duty to
25 serve reasons mostly. You know, you might

1 actually having a more disperse system that's a
2 little more geographically targeted.

3 So I just want to drive home a couple of
4 points and I want to tell a quick story. I am not
5 an engineer and that's partially why I am not
6 talking about technology. I have a graduate
7 degree in public policy. My first job out of
8 graduate school I worked for the White House
9 Budget Office and actually worked on health care,
10 the Medicare program.

11 And I was over at the old executive
12 office building. They have these meetings at the
13 Indian Treaty Room, which I always found ironic,
14 talking about a budget in the Indian Treaty Room.
15 And we were briefing the director of the Office of
16 Management and Budget and he asked a question, he
17 asked a question of three people. There was his
18 immediate subordinate, there was an economist and
19 there was an old-time, wily bureaucrat.

20 And he said, how much of GDP will the
21 health care budget consume next year? That was
22 his question. And his second in command said,
23 well, I think it's going to be about ten percent.
24 And the economist said, well, you know, it really
25 depends. The population is going up this way, the

1 economic indicators are this. It could be ten
2 percent, it could be twelve percent, I don't
3 really know. You know, one hand or the other hand
4 kind of thing. The wily bureaucrat kind of leaned
5 in and said, how much do you want it to be?

6 It was a good answer. And I think
7 that's where we're going with distribution
8 planning. How much do you want it to be? How
9 large a system do you want, what do you want it to
10 consist of?

11 We have kind of predicated our utility
12 system and our transportation system and our
13 health care system and our water system in the
14 state on building things for people as they come,
15 right. We have a duty to serve. We have a duty
16 to build roads, we have a duty to provide them
17 with electricity, we have a duty to provide them
18 with water, kind of in a passive way. And
19 increasingly we know energy-efficiency, water
20 conservation, demand response, toll roads, that's
21 shifted but we haven't explicitly acknowledged it.

22 And what I am seeing in distribution
23 planning is we're in charge of how much
24 electricity is going to be provided and in what
25 kind of way. And we have tools at our disposal to

1 influence that, whether it be through pricing,
2 through microgrids, or whatever. So to me that's
3 a fundamental change in distribution and planning
4 that could be happening.

5 And I'll give you more examples. I
6 mean, I think for example in my hometown of San
7 Francisco it is already happening in a crude way.
8 Citizen pressure closed the Hunters Point power
9 plant there and is leading probably to the closure
10 of the Potrero power plant. Essentially a public
11 call for a different generation mix, which then
12 has cascaded down into calls for different types
13 of distribution systems, energy efficiency, demand
14 response. And I guess in San Diego they may be
15 doing the same thing.

16 So that's planning. And again, I'm just
17 giving you a concept. I'm not going to go any
18 further or deeper than that.

19 Let's talk about communication real
20 quickly. I mean, we're going to have smart meters
21 everywhere. We're going to be able to communicate
22 with customers. But the question is, what is the
23 content of that communication? That's sort of the
24 question that remains not quite answered that we
25 all might have strong ideas about it. We are soon

1 going to be able to communicate with customers in
2 a two-way way. That's exciting. But is it going
3 to be like TV 50 years ago, one show, or will HBO
4 pop up somewhere? What does this look like?

5 I think one clue of this is that 50
6 years ago with telephones we had party lines,
7 right. So you got on the phone and you heard
8 someone -- it never happened to me because I was
9 two young but, you know, you got on the phone and
10 someone is talking and you had to get back off the
11 phone.

12 Well, that's happening in the
13 distribution system. Someone is on the phone.
14 Someone is using the distribution system. And if
15 you knew that they were on, your neighbor was on,
16 you might be willing to get off if that was
17 communicated to you.

18 Or if you knew in the case of demand
19 response programs, you know, that if you got off
20 the state wouldn't have an outage, you know, maybe
21 you would do your part. So there's a lot to say
22 about communication and I think it's beyond
23 technology. We have the technology, the question
24 is what are we going to do with the technology.

25 And finally is, how do consumers

1 participate in in this system? Right now our
2 examples are photovoltaics and demand response.
3 That's how people can participate as well as in
4 pricing. These are crude things. I think we'll
5 look at the current transition that we're going
6 through with the utilities similar do we see that
7 we see the solar industry in the 1980s. We're
8 kind of moving through it.

9 I just want to point out that people
10 critique both photovoltaics and demand response
11 saying that they are only being adopted because
12 they are heavily subsidized or they are being
13 forced down people's throats. But I think it is
14 important to acknowledge that a PV system that
15 costs \$50,000 that you pay \$25,000 for on your
16 home, you still pay \$25,000. And that will never
17 pay off, frankly. I mean, it will pay off 20
18 years from now when you've moved twice, right.

19 So we have to acknowledge that there are
20 customers out there who are reaching into their
21 pockets and they are paying to participate in the
22 electric utility system. That is important and
23 that is going to continue.

24 So I think the question then becomes,
25 with the technology that we are talking about how

1 do we, how do we match these things together? How
2 do we use the technology in coordination with
3 distribution planning, with communication with the
4 customers in a way that gives people opportunity
5 to effectively contribute to the grid?

6 And then I'll close by a comment on what
7 Russ said about people feeding at the trough. I
8 mean, again, as a customer you see these stovepipe
9 regulatory processes where generation gets treated
10 one way, transmission gets treated another way,
11 distribution gets treated another way. And
12 essentially it looks, it seems like we are pouring
13 money into these things, just from a consumer's
14 perspective. Whether that's analytically true I
15 can't really comment on it, I haven't examined it,
16 but it looks like we're pouring money into these
17 things.

18 If the world is truly shifting towards
19 distribution, or let's call it microgrids, then we
20 need less of something else, right? If we have a
21 lot more distribution that is able to handle
22 itself through DG, DER, energy-efficiency, then
23 why do we need all this transmission over here?
24 Or why do we need these big, thick sources of
25 generation over there? We might need some of it

1 somewhere but at some point there needs to be a
2 system approach to understanding what this whole
3 beast is going to look like.

4 And I go back to the story I told you
5 about OMB. What do we want this to look like?
6 There is a value to a microgrid that is beyond
7 just does it help the distribution system. It's
8 also about society and institutional structures
9 and economic benefits.

10 And I thank you for listening. Any
11 questions?

12 ASSOCIATE MEMBER GEESMAN: Yes, Steven,
13 if I may. You're not starting from a clean slate,
14 a clean piece of paper, you've got a legacy
15 system. That is especially true in the regulatory
16 agency part of the jungle. You've got agencies
17 with discrete, sometimes overlapping
18 responsibilities but a particular focal point.

19 You've got in California three investor-
20 owned utilities that serve roughly 70 percent of
21 the load. A tremendous level of historic invested
22 capital. And the way in which their shareholders
23 are paid is a return on what's calculated to be
24 their investment. Your future paradigm, shifting
25 definitions of duty to serve, a variety of new

1 relationships. How does the shareholder of any of
2 those three investor-owned utilities get paid?

3 MR. MOSS: You know, that's a very good
4 question and let me take two steps back and then
5 try to address it. One is, and I think it was
6 Russ that mentioned that, you know, they're having
7 employment problems. You know, they're going to
8 lose good people and they need to hire up and
9 there are not enough people being graduated from
10 these schools in order to fill these slots.

11 Well what comes to my mind is, who do we
12 want to fill those slots? This is a decision
13 point in a way. Like do we want an old-time
14 entomologist at the University of California or do
15 we want something more like a bioethicist? I
16 think it's an open question for the utilities and
17 only the utilities can really answer that in the
18 context of regulation.

19 Luther mentioned that we need successes,
20 I believe. We need successes out of the box. I
21 think the state has had enough experience with
22 grand schemes to try to change things and
23 resulting in grand problems.

24 I'm a big fan, and this is what you guys
25 actually have paid us to do, of smaller scale,

1 test bed-type approaches where you can actually
2 demonstrate effectively that whatever it is, the
3 system that you're trying to do, works. So in our
4 PAC meetings I brought up San Francisco as an
5 example of a microgrid and there was dispute like
6 well that's not really a microgrid. Maybe it
7 could be a microgrid, I don't know.

8 But I think that the utilities investing
9 in a small way in projects that demonstrate
10 whether it's 14,000 homes or San Francisco or an
11 irrigation district. And I think you asked the
12 question about ownership of, you know, these
13 infrastructure materials. Which if they did own
14 or had a relationship with they do profit from.
15 That there is no reason why the utilities can't
16 feel like they are profiting and the shareholders
17 are getting money from the evolution as it occurs.

18 If that's a reasonable answer.

19 ASSOCIATE MEMBER GEESMAN: So you see
20 the utilities as a permanent feature on the
21 landscape.

22 MR. MOSS: Well, the utilities are in
23 ascendance, let's be honest. The utilities are on
24 top right now. The regulators are trying to, you
25 know, manage utilities the best they can. Whether

1 that's appropriate or not I can't comment but I
2 think it's the reality. It's that we are looking
3 to the utilities to lead on this one and the
4 regulators are trying to nudge them in the right
5 direction.

6 ASSOCIATE MEMBER GEESMAN: Thank you.

7 PRESIDING MEMBER PFANNENSTIEL: Steve, I
8 have to say that I really agree with your approach
9 and I think that you're right. It is heading in a
10 direction and we are watching it happen. And
11 perhaps part of the reason we are all here today
12 and we are all party to the policy report is
13 trying to get ahead of it and shape some of it.

14 And I further agree that it's not just
15 about the technology. But I am a little concerned
16 still, there doesn't seem to be very much
17 discussion of cost. And clearly given different
18 answers to the what do you want it to look like
19 question, have different price tags associated
20 with them. As Commissioner Geesman pointed out,
21 different winners and losers in terms of
22 profitability. But I think from a customer
23 standpoint probably sort of significantly
24 different costs.

25 And as you go so many years into the

1 future then clearly this is a transition, it is
2 not a, it is not a point where it is all going to
3 happen quickly. We can shape but how do we get
4 ahead to look at the costs? And the costs will be
5 somewhat driven by the technology. You know, we
6 get back to the technologies. It's going to be
7 somewhat driven by that. So how do we think about
8 that? How do we build in the various scenarios of
9 different technology applications and adoption
10 rates and what is it that customers are going to
11 be willing to pay for?

12 MR. MOSS: Yes, that's really hard,
13 that's really hard. And you know, you see it, you
14 know, the presentation by the San Diego -- You
15 know, whether or not it's worth having a microgrid
16 approach. And you know, I was trained as an
17 economist and one wonders what assumptions are
18 behind every one of those numbers. Not to
19 criticize that study but we all know how those
20 studies work.

21 I think that right now, right now we
22 have an opportunity. This is an evolution taking
23 place that may become a revolution down the road.
24 You know, five to ten years from now. Right now I
25 think that there is an opportunity for the

1 utilities and the regulators and you Commissioners
2 to be piloting aggressively these technologies in
3 the context of what the institutional or social
4 structure it is that you want to experiment with.

5 In other words, I know that the Energy
6 Commission has a mandate to focus on technology
7 and really tries to drive its research in that
8 direction. But if you can place that technology
9 into a context, a regulatory context or a social
10 context that you think might be the future or you
11 might want it to be the future. And you can
12 experiment with that in interesting ways
13 throughout different service territories. I think
14 that will give you the opportunity when the time
15 comes to be able to make right choice.

16 You know, if we had smart meters in
17 every household in Davis right now we'd know what
18 we can do with smart meters, right? Well we don't
19 so they're being rolled out on a mass scale. We
20 have a lot of ideas about technology and we know
21 what's kind of perking out of the water. Let's
22 look at them in a real world setting and evaluate
23 how that looks. And on that basis then we can
24 develop analyses to tell us what it's going to
25 cost. That's my best approach to it.

1 Other than that you just have to like
2 take a big stick and whack on costs every once in
3 a while and that's pretty crude.

4 PRESIDING MEMBER PFANNENSTIEL: Thank
5 you.

6 MR. MOSS: Thank you.

7 MS. KELLY: Any other questions? No.

8 Is there any on the, on the telephone
9 does anybody have any questions? None.

10 Okay, thank you, Steven.

11 Our next presenter is Eric Lightner from
12 DOE. Eric has worked as a program manager for
13 advanced technology development at the -- I'm
14 sorry. Eric is program manager for advanced
15 technology development for the Department of
16 Energy for the last 16 years.

17 Currently Mr. Lightner is the program
18 manager for Electrical Distribution and GridWise
19 programs with the Office of Electricity Delivery
20 and Energy Reliability. This program has been
21 chartered to modernize both the hardware and the
22 software components within the distribution system
23 in order to address reliability and security
24 concerns as well as to help move the electric
25 delivery system into the information age.

1 Eric has been a member of my Program
2 Advisory Committee from the beginning. I really
3 have to say that we appreciate the support of the
4 Department of Energy to send him out here. Your
5 boss is Pat Hoffman?

6 MR. LIGHTNER: Yes.

7 MS. KELLY: Yes. Pat Hoffman has been
8 very supportive of this program and some of the
9 other research we're doing and we're working hard
10 to develop some new collaborations, especially
11 looking at Smart Grids, intelligent grids going
12 into the future. Thanks, Eric.

13 MR. LIGHTNER: Okay. Thank you, Linda.
14 I appreciate the opportunity to come here and
15 share with you some of the research that DOE is
16 currently funding. Again, my name is Eric
17 Lightner, I am with the Office of Electricity
18 Delivery and Energy Reliability. This office is a
19 relatively new office, we're two, three years old
20 or so. We basically were formed right after the
21 2003 blackout to started addressing some
22 reliability concerns.

23 I thought I'd just give you some context
24 for the technologies that I am going to discuss
25 and introduce to you as far as within our office

1 and what our office does in general. So again,
2 Office of Electricity Delivery and Energy
3 Reliability. We have three main suboffices,
4 research and development, which is where I work in
5 and what I'm going to talk about today,
6 permitting, siting and analysis group, and
7 infrastructure security and emergency response
8 group.

9 The emergency response group, they're
10 the ones that do deployments and do work with FEMA
11 and all these other organizations when there's
12 some sort of emergency that involves energy. The
13 permitting, siting and analysis group, these are
14 the guys that worked on the EPAC 2005 requirements
15 and deliverables for the department as well as the
16 corridor designation study that I'm sure you all
17 have knowledge of, and then the research.

18 And we have four main areas of research.
19 These are just the budget titles, more or less.
20 Visualization and controls, high temperature
21 superconductivity, energy storage and distributed
22 systems integration. And what I am going to
23 present today is some of the projects that are
24 funded under the visualization and control piece
25 as well as the distributed system integration

1 piece, which more or less represent what research
2 we're doing in the distribution area.

3 So in the distribution area really our
4 goal is to modernize our distribution grid
5 infrastructure and operations from the substation
6 all the way down to the consumer. So we're really
7 looking at technologies and the integration of
8 technologies that can flatten the load curve,
9 reduce the peak.

10 A summary of our funding over the last
11 few years. This year we have approximately \$8.7
12 million invested in the projects. And I might
13 point out that this year we got no
14 congressionally-directed projects, which was -- it
15 looks like our budget was decreased but actually
16 it's an increase if you do the math here and
17 subtract out the congressionally-directed
18 projects. So, you know, sometimes not passing a
19 budget in October is a good thing and in this case
20 it was.

21 This just shows how that funding is
22 currently distributed amongst the different areas
23 that we invest in, architecture and standards,
24 monitoring and load management, advanced
25 distribution operations, modeling and simulation,

1 integrated demonstration R&D and we have a little
2 bit of money going out into a solicitation this
3 year. So I'm just going to, you know, do a
4 whirlwind tour here of some of the technologies
5 that we are currently investing in.

6 And hopefully you'll see that a lot of
7 them address some of the concerns that we have
8 heard here today, some of the needs that we have
9 heard expressed by the different utilities. So it
10 has actually been a good thing, I think, for me to
11 sit here and listen to the three utilities that
12 presented today. It makes me feel good about what
13 we are currently investing in. I think we are
14 starting to address some of those areas. You
15 know, we're a far cry from addressing them all but
16 we are starting to address some of them.

17 The GridWise Architecture & Standards.
18 The gridwise architecture group is a group that's
19 really focused on starting to address well what
20 are the requirements for interoperability. How
21 are we going to, you know, enable
22 interoperability. Not only in the utility
23 enterprise but across different enterprises. So
24 for example when the utility equipment needs to
25 talk to a building's automation system, how is

1 that going to occur. What sort of information
2 needs to go across that boundary.

3 We are also looking at, we're leading
4 and facilitating the IEEE 1547 standards. So not
5 only the standards development but we're also
6 looking at validation and testing of those
7 standards as well as working with different areas
8 of the country to have them adopt IEEE 1547 in
9 some manner.

10 So again, the GridWise Architectural
11 Council is this group of volunteers from industry
12 that we're just facilitating to begin to think
13 about what are the issues in interoperability.
14 And how it may start to address those and put some
15 principles or parameters in place that we all can
16 agree to so that when we start to integrate these
17 systems we have a little bit of a roadmap or some
18 guidelines to do that.

19 So in monitoring and load management
20 technologies we have a few projects ongoing there.
21 The one I highlight here, the Cable Diagnostic
22 Focused Initiative is the one I'll speak of
23 further. This is a project where we're looking at
24 basically in-lab and in-service testing of
25 diagnostic technologies, cable diagnostic

1 technologies. We are trying to really baseline
2 what their capabilities are.

3 So existing diagnostic technologies,
4 both in the lab with some samples that have been
5 taken out of utilities and sent to the lab. We're
6 looking at you know, what do these different
7 technologies, how can they perform in diagnosing
8 how they failed. We are also looking at in-
9 service testing as well.

10 So the bottom line with this project is
11 we are trying to produce information for the
12 utility industry that we feel would be helpful for
13 them as far as exactly what are the capabilities
14 for the different diagnostic techniques and on
15 what kinds of cables will they work or not work.
16 So it's more of a baseline kind of effort.

17 What we hope to get out of it, though,
18 is to identify gaps in the technology and
19 hopefully that will lead to areas that we need to
20 invest research to get the additional capability
21 that we're lacking in order to really come up with
22 some better techniques to, you know, predict cable
23 life.

24 So advanced distribution operations. In
25 the DER integration area we have a project at DTE

1 which is looking at integrating DER into their
2 system for economic and for reliability reasons.
3 they currently are operating both customer-owned
4 and utility-owned DG into the midwest ISO energy
5 market.

6 The one I have highlighted here is the
7 3G System of the Future. This is a pretty
8 interesting project. I didn't have enough time to
9 prepare a slide on it unfortunately but this
10 project is looking at software agents and how we
11 might utilize them as the platform to integrate DG
12 and other resources into the operations of the
13 grid. You know, we have this vision of
14 interoperability and we're not really sure how it
15 is going to work so we figured we'd test at least
16 this software agent platform to see how might that
17 help bring about integrating some of these
18 resources into the distribution operation.

19 For the modeling and simulation projects
20 we have several of those ongoing. The one that I
21 am going to talk about is the results of the plug-
22 in hybrid impact analysis that we funded at
23 Pacific Northwest National Laboratory.

24 So this was kind of an interesting
25 project. I guess about a year and a half ago or

1 so we started kicking around the idea, you know,
2 what if these plug-in hybrid things are for real
3 and what kind of impact might they have on the
4 electrical delivery system in this country. So we
5 commissioned the study at PNNL and came up with
6 some rather interesting results.

7 The parameters around this were well
8 what is the maximum number of plug-in hybrids. If
9 every car out there, every light duty vehicle out
10 there was a plug-in hybrid. Do we currently have
11 capacity to support charging of those light duty
12 vehicles. So that was really the case we looked
13 at, that limiting case. With today's
14 infrastructure and tomorrow's 100 percent plug-in
15 hybrids, could we meet that demand?

16 You'll see here that net petroleum
17 imports are 60 percent in 2005. Of that gasoline,
18 light duty vehicles represent 73 percent of those
19 net imports. And the results of the study
20 basically showed that up to 84 percent of all
21 light duty vehicles could now be recharged with
22 the existing capacity if you use a technique that
23 is valley-filling.

24 So you charged -- We looked at two
25 scenarios. You charged only at night and the

1 other charging scenario was 24 hour valley-
2 filling. So whenever there was capacity available
3 you were able to charge. So that number was
4 actually much higher than we thought it would be.

5 Again, this is the technique that we
6 used. An average peak day load curve here. And
7 the idea of valley-filling would be to charge your
8 vehicles whenever there's capacity available. So
9 if you utilized 100 percent of its capacity what
10 would that mean for charging of vehicles?

11 And some of the assumptions here are
12 important to note. That constrained valley, we
13 excluded hydro, renewables, nuclear and peaking
14 plants from being able to be utilized as the
15 resource to charge.

16 Because our reasoning was, hydro,
17 renewables and nuclear, they're used all the time
18 whenever they're available, period. So they are
19 not available for on-demand valley-filling like
20 the other sources would be. And the reason we
21 threw out peaking plants was because if you had to
22 charge with a peaking plant you basically just
23 busted the whole economics of the situation.

24 So we did this on a regional basis, NERC
25 regions. And it is interesting to note that

1 regions like ERCOT, they could charge -- the blue
2 is the 24 hour valley-filling and the red is the
3 nighttime so six p.m. to six a.m. You'll notice
4 that ERCOT could support 80 percent of every
5 single light duty car now on just nighttime
6 charging and almost 150 percent if they charged
7 all the time.

8 So it's rather amazing. And you also
9 might note that California is one of the worst off
10 as far as the ability to charge with the existing
11 capacity that exists in this region. Which is
12 amazing because this is probably where the initial
13 adoption is going to occur.

14 So here is a more detailed one of this
15 NERC region. You can see that there is really not
16 a lot of capacity here to meet the demands of
17 plug-in hybrids.

18 This is the results of the emissions
19 analysis. We were a little bit surprised at this
20 too. We thought it would be a little bit worse
21 than this but basically this is a ratio of
22 electric vehicle to gasoline vehicle emissions.
23 So anything, you know, under one is a good thing.

24 And really only, you know, particulates
25 and SOx turned out to be above one over here. So

1 it's really a much better picture than we thought
2 it would be. And the particulate emission, we
3 thought that was handled more easily because what
4 you're doing is you're moving the pollution out of
5 the city, out of where all the congestion is, out
6 of where the cars are and you're moving it to a
7 more rural location.

8 But it's a point source now, it's just a
9 generator. And that would even give us more I
10 believe argument for investing in clean generation
11 technology, clean central generation technology
12 like clean coal. Because we have moved that
13 pollution out of the cities into a remote location
14 where we can address it as a point source, rather
15 than trying to address it out of the tailpipe of
16 millions of cars. So that's actually not as bad
17 as it might seem.

18 Where we're going with this. This
19 research ended at the end of last year and our
20 final report just came out in December, I believe,
21 of this past year and we're getting ready to
22 embark sort of the next round of investigation in
23 this area. We want to start to look at what are
24 some realistic adoption scenarios.

25 Instead of saying, well what if every

1 car was a plug-in hybrid could we support it,
2 that's a limiting case. Let's start to look at,
3 what are some realistic adoption scenarios. So
4 we're working with a major utility, DTE, as well
5 as GM and Ford as a team to really come up with
6 some more realistic adoption scenarios. To look
7 at more in-depth what the technologies are, what
8 really the charging requirements are going to be
9 for different classes of vehicles and just do a
10 much more in-depth analysis in this area.

11 So some of the integrated demonstrations
12 that we're doing, I'm going to talk about two very
13 briefly. One is a project supported by the
14 Advanced Grid Applications Consortium. That is a
15 consortium that DOE has funded for the last two
16 years. It's a consortium of utilities that are
17 looking at technologies that are very near
18 commercialization. So they just need that extra
19 kick, so to speak, to get over the hump and become
20 a commercial product.

21 And I am also going to tell you a little
22 bit about the Modern Grid Initiative Developmental
23 Field Test that is ongoing or that is going to on-
24 go in Morgantown, West Virginia.

25 So this is one of the Grid Application

1 Consortium technologies. This is a very
2 interesting device and what this is is an
3 autonomous storm detection adaptive relay. What
4 it does is it's a device that you put at a
5 substation. And it senses when there's a storm in
6 the vicinity and it changes the relay settings at
7 the substation to a storm mode rather than a
8 normal mode and it does it autonomously.

9 So instead of, you know, sending a crew
10 out to change the protection relays manually and
11 then after the storm passes, you know, forget to
12 turn them back or turn them back a couple of days
13 later, this does it autonomously. So it detects
14 when a storm is in the area, changes those relays
15 for you and changes them back when the storm is
16 not in the area.

17 It sounds simple but it has really been
18 effectively demonstrated now at about six
19 locations in FirstEnergy territory and it has
20 saved a countless number of fuses and a countless
21 number of labor hours of sending people out to
22 change these settings. So it's really been -- It
23 sounds simple but it has worked very effectively.

24 Now I have to go to that other. I had
25 to have two presentations apparently.

1 ASSOCIATE MEMBER BYRON: So while you're
2 switching, Mr. Lightner, can I ask, what is the
3 detection scheme? Is it barometric pressure or
4 some -- I have not heard of this but it sounds
5 like a great idea.

6 MR. LIGHTNER: It's basically weather
7 detection equipment, that's correct. So it's
8 pressure detection. I believe it's -- I think it
9 has wind as well. A couple of other weather
10 devices and that's it. And it's connected
11 directly to the settings on the relays. It's
12 rather ingenious, very simple.

13 ASSOCIATE MEMBER BYRON: Thank you.

14 MR. LIGHTNER: This is the project I
15 wanted to tell you about. It's called the
16 Morgantown DFT, Developmental Field Test. It's a
17 project under the Modern Grid Initiative. That's
18 a team at SAIC that has, includes EPRI as well as
19 DOE as well as the GridWise Architecture Council
20 and a few other of these Modern Grid Initiative
21 type people that have come together to design this
22 demonstration.

23 And what it is going to look at is the
24 phase one is autonomous reconfiguration of
25 circuits to be able to recover much more quickly

1 from faults. Phase two is going to take that one
2 step further, not only to do autonomous
3 reconfiguration but what if we did autonomous
4 reconfiguration with integrating DG and demand
5 response into some of these areas.

6 So to even further limit not only the
7 number of outages but the number of people
8 affected by an outage. So the idea here is to
9 isolate a fault as quickly as possible and to
10 minimize its effect on outages for the least
11 number of customers possible. And I am just going
12 to flip through.

13 So phase one is just the Autonomous
14 Dynamic Feeder Reconfiguration. So dynamically
15 collect data from distribution feeders and, in
16 case of a fault, will automatically isolate the
17 fault and restore electric service using available
18 capacity from adjacent feeders. And that's the
19 unique part. So it's going to in real time
20 calculate what that capacity is on an adjacent
21 feeder and determine how much of the faulted
22 feeder, how much of that load it can pick up. And
23 then, you know, the different tie lines would be
24 closed or opened accordingly.

25 So hopefully this will significantly

1 improve reliability indices, defer or avoid some
2 planned capital investments. And actually in this
3 case this is going to be, they wanted to add a new
4 substation, Allegheny Power that is, wanted to add
5 a new substation to support an industrial park.
6 And if this project is successful they will not
7 have to add that substation so they will avoid
8 that upgrade for at least several years.

9 So this is a picture of Senator Byrd's
10 new golf course in West Virginia. Not really,
11 this is the DFT. So the way it's going to work is
12 these are two circuits on this Westran substation
13 here. And I'm just going to run you through a
14 real quick demo of how it might work, how it
15 hopefully will work.

16 So there's a fault in Zone 2 that's
17 detected. The entire circuit trips at the
18 substation. Load break switches open isolating
19 Zone 2 from the circuit. The substation circuit
20 breaker then closes. Zone 1 is now energized.
21 The load break switch between Zone 3 and 4 opens.
22 The load break switch between Zone 4 and adjacent
23 feeder closes so now Zone 4 is re-energized. The
24 load break switch between Zone 3 and adjacent
25 feeder closes so now Zone 3 is re-energized. So

1 all that is going to happen autonomously based on
2 what the capacity is in those adjacent feeders.

3 So, you know, again, the next step on
4 that project is after we can show that this
5 autonomous reconfiguration really improves the
6 reliability indices there then can we take that
7 one step further. Now can we start to integrate
8 customer-owned DG. Maybe there's some customer-
9 owned DG in that faulted zone that could pick up
10 part of that zone or what have you. So we're
11 going to start to look at how can we utilize more
12 and more resources on those circuits to not only
13 improve the reliability but to, you know, make
14 customers more happy.

15 One thing I do want to mention here was
16 a solicitation that we just released I guess it
17 was about two weeks ago now. We are hoping to
18 award, make about six awards ranging in size -- we
19 have about \$30 million to invest total over the
20 five years. It is not a whole bunch of money but
21 hopefully it's enough to do some demonstrations
22 like the DFT where we can show added value.

23 We anticipate making the awards in
24 September but based on history I would say it's
25 going to be a little bit after that. It takes a

1 long time for these things. And that is going to
2 be released and administered through the National
3 Energy Technology Laboratory in Morgantown.

4 Another part of the solicitation or what
5 the solicitation is about, it is basically about
6 integrating resources into the utility operations.
7 So how can we, again, bring to bear a lot of these
8 resources and a lot o these technologies that we
9 have been developing over the years into use, into
10 operation in the utility.

11 In addition to that we also would like
12 to see some developmental work in low-cost sensors
13 for cables, cable application, advanced monitoring
14 and distribution automation kinds of projects and
15 also to begin to look at consumer information
16 gateway development. So two-way communication
17 between load-serving entities and electric loads
18 within the consumer premise.

19 So I do want to briefly tell you about
20 this GridWeek event that we had two weeks ago.
21 This was an event that, you know, we thought it
22 was, you know, past due. That we needed to start
23 really getting all the different stakeholders
24 involved in this industry together and get them on
25 the same page and moving forward in the same

1 direction as far as grid modernization goes.

2 You know, there's some many different
3 initiatives and competing groups and whatnot out
4 there that it's really hard to get your arms
5 around all this and basically it seems to be
6 counterproductive at this point. We're not really
7 all moving in the same direction.

8 So we thought it was overdue to have
9 some sort of event where we got all these
10 different stakeholders together and started saying
11 hey, what are the issues out there and how can we
12 move forward together. That's really what
13 GridWeek was about.

14 It more than exceeded our expectations.
15 We had 634 participants. We thought we'd get
16 around 300, 350 so almost double what we thought
17 we'd get, we were very pleased. Which just goes
18 to show that people are listening. These issues
19 are now being discussed at very high levels.

20 Just a week after this event there was a
21 hearing on Capitol Hill on Smart Grids. Tomorrow
22 there is another hearing on Capitol Hill on Smart
23 Grids. So I think we were successful in raising
24 the attention of these issues over the past couple
25 of years and it is finally starting to pay off.

1 People are listening, people realize that hey,
2 we've got to start doing something about this
3 stuff. So that's a good sign.

4 So this just pictorially shows you that,
5 you know, what are you talking about when you say,
6 hey, we're trying to get all these different
7 groups together. Just look at that. It's a mess
8 of all these different competing groups. Nobody
9 really cooperating or talking. What we are trying
10 to do is begin that discussion. Let's get
11 everybody on the same page, Let's start working
12 together.

13 And specifically my program works with a
14 lot of different groups on the technologies that I
15 just went over with you on and this is just a
16 listing of those. So we work with the GridWise
17 Alliance, which is an advocacy group for Smart
18 Grids. We work with the GridApp Consortium, we
19 work with NEETRAC, which is -- they're the ones
20 doing the cable diagnostic focus initiative that I
21 talked about briefly. Of course we work with the
22 PIER program, the IntelliGrid group as well as the
23 Grid Modernization Collaborative.

24 So that's all I have for you today.
25 This is my contact information. Feel free to

1 contact me with any questions you might have now
2 or later. Thank you.

3 PRESIDING MEMBER PFANNENSTIEL:
4 Commissioner Byron.

5 ASSOCIATE MEMBER BYRON: Thank you.

6 Mr. Lightner, this is like old home
7 week. I see a bunch of the members of the Program
8 Advisory Committee that I was once a member of and
9 I just wanted to acknowledge. I know Tom is on
10 there and Russ and there may be others too.

11 I don't know a lot of the other program
12 advisory committees but this is one of the most,
13 it's got to be one of the most loaded ones that we
14 have in terms of capability. This is really
15 interesting stuff and I didn't really know that
16 you were involved in these activities at DOE.

17 And I'm just curious, when I look back
18 at your presentation and you were talking about in
19 phase one all the goals that were included there,
20 is power quality really something that is being
21 addressed by the Smart Grid? I mean, is that just
22 a term that we throw around here? Is there really
23 something for, let's say, the commercial/
24 industrial consumers that can't stand
25 interruptions of more than, you know, a quarter of

1 a cycle or something? Are we really addressing
2 that kind of issue with the Smart Grid?

3 MR. LIGHTNER: Well I think yes and no
4 is the answer to your question. The answer is yes
5 we're investing in energy storage technologies,
6 which I think will have a big impact, or hopefully
7 will have an impact that address power quality
8 issues. Now whether you consider those to be part
9 of the Smart Grid definition or not, that's what
10 is debatable, I believe.

11 But we are, we do have a relatively
12 modest energy storage program that we hope, you
13 know. And it's utility scales energy storage so
14 it's not, you know, a smaller consumer scale
15 energy storage. That it will have a positive
16 impact on power quality.

17 ASSOCIATE MEMBER BYRON: Okay. Thank
18 you. And actually thank all of you. Like I said,
19 I just think this is one of the most
20 technologically loaded research advisory groups
21 that we have.

22 PRESIDING MEMBER PFANNENSTIEL: Any
23 other? Thank you.

24 MR. LIGHTNER: Thank you.

25 MS. KELLY: Just one minute, Eric. On

1 the telephone are there any questions? Nothing.

2 Thank you, Eric.

3 Our next speaker is going to be Frances
4 Cleveland. Frances Cleveland is the president and
5 principal consultant for Xanthus Consulting
6 International. She has managed and consulted on
7 information and control systems projects for power
8 electric utilities for over 30 years covering
9 SCADA systems, distribution automation, substation
10 automation, distributed energy resources,
11 automated metering infrastructure and energy
12 market operations.

13 Frances also is the chairperson of the
14 IEEE wireless working group developing recommended
15 practices for wireless communications and power
16 system operations. Frances.

17 MS. CLEVELAND: Thank you, thank you
18 very much.

19 I'm afraid we're going to at this point
20 head downward into the bowels of technology rather
21 than up at the higher plane. But on the other
22 hand I would like to say that some of the stuff
23 that I would like to talk about really does help
24 to address Steven Moss's issue of what do you want
25 it to be. Let's see, do I just click? No, I do

1 something else. Up and down, okay. Down, all
2 right, thank you.

3 So I am going to address four issues.
4 Basically I am addressing system integration or
5 the issues of interoperability. So talking about
6 the communications infrastructure, or more
7 generally speaking, the information infrastructure
8 that you need in order to make whatever it is that
9 you want it to be actually happen. Because this
10 is the underpinnings for everything that
11 ultimately you may want to do. Excuse me.

12 So I am going to discuss this,
13 obviously, in the context of distribution and DER
14 as well as AMI. I am also going to give a very
15 brief overview of what system integration and
16 interoperability is because sometimes just the
17 words themselves make people's eyes glaze over.
18 And then I'll talk about some challenges and
19 activities that are ongoing in this arena. And
20 then really trying to hit the potential role of
21 California in addressing these interoperability
22 issues.

23 There are really seven principal
24 characteristics of a fully modern grid. Now this
25 is again addressing it from a technological point

1 of view. But there is the ability to rapidly
2 detect, analyze, respond and restore from
3 perturbations. All of this requires
4 communications information.

5 The ability to incorporate consumer
6 equipment and behavior in the design and operation
7 of the grid.

8 A grid tolerant of security attacks.
9 This is not just terrorist attacks, this is
10 inadvertent mistakes by people. People forgetting
11 to close doors or to push some button or to turn
12 on the system that would have determined that
13 indeed there was a problem August 14, 2003.

14 In addition a grid that provides a
15 quality of power consistent with consumer and
16 industry needs.

17 A grid that accommodates a wide variety
18 of local and regional generation technologies,
19 including green power.

20 A grid that fully enables maturing
21 electricity markets. So all of this is market as
22 well as the technology of getting, you know, watts
23 to people.

24 And a grid that continually optimizes
25 its capital assets while minimizing O&M costs.

1 And this all comes from the program to
2 accelerate grid modernization. That's a direct
3 quote from that. And in reality, advanced control
4 and communications technologies integrated with
5 the utility distribution network provide the glue
6 for achieving the requirements of the modern grid.
7 So this is really saying, again, whatever it is
8 that you want to do requires this information
9 infrastructure glue.

10 In one sense my thunder was stolen here
11 already by virtually all three utilities saying
12 the same thing but that the distribution systems
13 account for 90 percent of the outages for
14 customers. So they really need to be addressed if
15 you're talking about reliability. So it's a
16 really critical issue to try to minimize that.

17 And less than 30 percent of the US
18 utilities have distribution monitoring and control
19 systems. In the past it just simply wasn't
20 thought worthwhile. There was just too much
21 distribution out there. You just had people
22 running around and fixing things manually.

23 The trouble is that with the increased
24 implementation of DER, demand response, AMI, doing
25 all of this manually is just not going to be

1 feasible anymore. It is just going to be an
2 impossible task. So even if you wanted to
3 continue doing this it wouldn't be feasible.

4 One sort of little picture that I like
5 is the idea that we have at this point not just
6 one infrastructure to manage. It is not just the
7 power system infrastructure anymore. What we also
8 have to do is to manage the information
9 infrastructure. They are so tightly intertwined
10 now that you have to look at them as one piece.
11 They are one thing that have to be designed
12 together, implemented together and managed
13 together.

14 Okay, I'm going to have a very, very
15 short tutorial on what is system integration. And
16 the reason is because a lot of people don't really
17 know what it is and this is a very high level one.
18 But I think it's worth seeing because it's
19 actually the same way that us geeks in the system
20 integration world actually talk about it.

21 So how did disparate human groups
22 communicate with each other? You've got Germans
23 speaking German, and I won't try to read it out.
24 The French speaking French, the Spanish speaking
25 Spanish and the Martians well, yeah anyway.

1 What has been decided, for better or for
2 worse, is that English is the common language. If
3 you go to any international conference English is
4 what is used. And this has been accepted because
5 it became virtually impossible to try to
6 translate, have simultaneous translations and
7 interactions that were going on in multiple
8 languages. I know it's still done at the UN but
9 in any technical conference there is one language.

10 Similarly in system integration we're
11 trying to establish common data languages for
12 interoperating among computer systems. As I said,
13 we use this term. We are talking about computer
14 languages, data languages. So it's not just a
15 question of making it simple, it really is how we
16 think of it so that we use standards.

17 In our case we don't have English, we
18 don't have a common standard language. We are
19 having to create them. And this is some of the
20 effort that is going on. And the creation is a
21 messy process because you have to get everybody to
22 agree.

23 We didn't have English so we're trying
24 to create Esperanto but, you know, we've got
25 different people. We've got not just the

1 Europeans we've got Chinese, we've got Africans,
2 we've got, you know, who name it. So we are
3 trying to create standards and we believe this is
4 the way that we are going to get that system
5 interoperability that we really need.

6 This actually comes from one of the
7 presentations at GridWeek that Eric was talking
8 about. That the US Senator Maria Cantwell in her
9 act that she is introducing on reducing demand
10 through electricity grid intelligence, it was
11 presented there. And it in part read that it:

12 "-- proposes a broad
13 definition of Smart Grid
14 technology, which includes
15 smart metering systems, demand
16 response systems, distributed
17 generation management systems,
18 electrical storage management
19 systems, distribution
20 automation system --"

21 And there were some others. There was also one
22 section in there that said Standards. And it
23 said:

24 "Standard-setting provisions
25 are considered to be vital to

1 ensure interoperability and
2 allow for smart appliances and
3 equipment."

4 She is talking in this case more about home
5 equipment but it's the same idea everywhere. And
6 then going down to the bottom:

7 "This section ensures that
8 Smart Grid systems and
9 components by different
10 manufacturers will in fact
11 someday be able to constitute
12 an electranet, Al Gore's term,
13 a community of intelligent
14 devices on the grid."

15 So breaking this down even further in
16 using the language metaphor. Okay, there's the
17 media. Many times when people talk about
18 communications that is really all they think about
19 is the media. Okay, are you going to use fiber
20 optics or are you going to use wireless, are you
21 going to use a broadband power line. What are you
22 going to use?

23 But there is a lot more to the
24 information infrastructure than that. There's
25 verbs and the grammar that goes along with that.

1 It tells you when to send, what are you
2 monitoring. Agents. The new idea of having grid
3 agents wandering around doing things. They're
4 verbs, they're going places, they're finding
5 things.

6 In addition to that you need nouns. And
7 nouns are the data and they're the measurements.
8 They're the raw data that you get. They're the
9 calculated data that you get. They're the files,
10 they're the stuff in the databases. It's all of
11 this stuff. Data management is a huge problem,
12 particularly now that you're getting tons and tons
13 and tons of data.

14 You've got to know what to do with it so
15 you've got to have applications. Users, whether
16 they're human but more often now computer
17 applications, that take that data and turn it into
18 information. Without that it's just lots and lots
19 of stuff coming and you don't know what to do with
20 it. So it has to be picked up and analyzed and
21 converted into information.

22 So what are the challenges of
23 interoperability? As I've said the standards can
24 provide the interoperability needed across
25 different systems. And some of the challenges

1 nowadays looking at the communication media
2 aspect, is WiFi wireless secure and reliable? Can
3 broadband power line be used and where? What is
4 the cost-effectiveness of different types of media
5 for distribution automation?

6 These are all issues that really do need
7 to be addressed that are not being necessarily
8 addressed outside the electric power industry.
9 You might think WiFi is, and to some degree it is,
10 but it really is not being addressed for the needs
11 of the electric power industry. So these are
12 issues that still need to be done.

13 Okay, if you're looking at the verb
14 side, the messaging. Security, cyber security is
15 a big issue. Security by obscurity is no longer
16 feasible. That used to be the thing, nobody cares
17 about what information is being passed around in
18 the power grid, but that is no longer the case.
19 There is espionage, there is possibly terrorism,
20 more likely there is some disgruntled employee who
21 gets in there and just tries to disrupt things as
22 they did a short while ago at Cal-ISO. So
23 security is a big, big issue.

24 Network management. As I said, you
25 can't just have data coming. You need to have --

1 You need to get that data to the right place in
2 the right time and only then can it be turned into
3 information.

4 Then protocol standards. Agreement on
5 the standardized interfaces between systems. This
6 might be where the grid agents come in. Where
7 they become part of the protocol standards.

8 But the data itself, the stuff that is
9 being carried along in the message, the data
10 management in itself is another whole issue. it
11 doesn't matter whether the data is going over
12 wireless or broadband or fiber optic. It doesn't
13 matter if it's going with grid agents or some
14 other kind of messaging protocol. It's the data
15 itself, that stuff, that information.

16 And the problem is that there is just
17 such a vast amount of it coming from different
18 vendors, coming from different utilities, coming
19 from different customers, the ownership of the
20 data is a big issue. It's no longer just the
21 utility owns all the data that it collects, it is
22 now coming from other areas.

23 How do you convert this? How to use it
24 effectively. And there's data modeling standards.
25 I won't get into that but there's a whole arena of

1 actually modeling data. Not just modeling the
2 power system but modeling data so that you can use
3 it more effectively.

4 And then the last area are the computer
5 applications. You know, we really need to move
6 from just seeing information come from different
7 items from the power system to a real-time
8 analysis of the distribution system.

9 I know there has been a lot of work that
10 has been going on in different arenas but not all
11 of it has been focused on the real-time aspect
12 where the real-time is looking at it within
13 seconds of something happening so that you can
14 actually do automated control of switches.

15 You can determine where the DER -- You
16 know, what is happening out there in the network.
17 Again, the utility is no longer really in control
18 so much as they used to be so the information
19 coming in is absolutely critical to managing the
20 operation so it has to be more real-time than it
21 used to have to be.

22 And then how to ensure power system
23 reliability, efficiency, customer service, safety,
24 environmental compliance that is going to come
25 with the greenhouse gases as well as other things

1 and access to the electricity marketplace. That's
2 the time of use, real-time pricing, any of these
3 other demand response type initiatives.

4 Okay, who is doing the research and
5 crating the standards needed to address these
6 challenges? And I'll start off by saying that
7 indeed there are a lot of groups, some of them
8 working with GridWise or through GridWise, many of
9 them working separately, who are developing these
10 standards. They all recognize that they're
11 needed. But standards are useless until they're
12 tested, validated, accepted by all of the relevant
13 vendors and users, implemented widely and possibly
14 even mandated.

15 Now one great thing about standards is
16 that there's so many out there to choose from --
17 It doesn't work that way. You have to have a
18 single set of standards or it won't work. It's
19 okay to have American English and British English,
20 that's good enough, but you can't have some very
21 strange variety of English, it doesn't work.

22 So the media is being handled, the
23 standards by vendors, utilities, associations.
24 The IEEE is doing a lot. The industrial
25 automation group ISA is doing a lot.

1 In the messaging, security and data
2 management we have, to be quite honest, a whole
3 bunch of this coming from the Internet and web
4 standards so we're picking up on that. Ethernet,
5 TLS, a lot of those terms that you might or might
6 not know. Many of them come from the Internet.
7 And that's fine and we can use them where we can
8 but not all of them are applicable to the power
9 industry.

10 The International Electrotechnical
11 Council, the IEC, developed standards, and I'll
12 say this carefully here, they developed standards
13 that are accepted by every country in the world
14 except the United States. So we get to pick and
15 choose which IEC standards we want to implement
16 but nobody else in the world does.

17 But anyway there is a tremendous amount
18 of work going on there. IEEE developed standards,
19 NERC developing particularly security-related
20 standards. EPRI is doing R&D, obviously DOE as
21 well.

22 Computer applications are typically more
23 the vendors and the utilities we be need the
24 standards to at least interface to them so we need
25 to have a better understanding of those.

1 What roles could California play in
2 addressing these interoperability challenges? And
3 I think it's again the same thing that I was
4 saying. California could study, test, validate
5 and promote interoperability standards.

6 It is very frustrating for somebody -- I
7 have been a consultant for 30-odd years and know
8 that there are these standards out there. There
9 are some really good standards out there. Many of
10 them are collecting dust as some paper document
11 somewhere. Others have been taken and sort of
12 half-implemented over here because well, it was
13 good enough, and what they have done is different
14 from what another vendor has done.

15 So there really needs to be a much more
16 concerted effort in handling the whole issue of
17 standards. I'm hoping GridWise will in fact do a
18 large part of that in this coordination. But it
19 needs study, it needs testing, it needs validation
20 and just promoting of the applicable
21 interoperability standards.

22 So for medial we've got wireless,
23 broadband power line carrier. In the messaging
24 and security we need, we could use the Internet
25 security where it's applicable but we need to take

1 a look at that and really validate it. IEC has
2 developed some standards along those lines and so
3 has NERC.

4 Data management is probably one of the
5 bigger, messier areas. There are some emerging
6 IEC and IEEE standards on data management but data
7 is really a vast area. And one person's data is
8 another person's junk and so it's really difficult
9 to get a handle on this. I think we are getting
10 there in the IEC and the IEEE work but it's going
11 to take a lot more, more effort.

12 And then in computer applications we
13 really need to get some more computer applications
14 running to do this real-time work. Once you've
15 got that, once you've got the real-time
16 applications running then you can decide what the
17 power system is really going to look like because
18 you've got the tools to manage it. That's
19 simplistic, I know I'm sort of speaking at the
20 high level there like Steven Moss but that's,
21 that's okay too.

22 Okay, so questions or comments on that?

23 PRESIDING MEMBER PFANNENSTIEL: No
24 questions from the dais?

25 ASSOCIATE MEMBER GEESMAN: I have a

1 question.

2 PRESIDING MEMBER PFANNENSTIEL: Yes,
3 Commissioner Geesman.

4 ASSOCIATE MEMBER GEESMAN: Frances,
5 looking at the way in which the transmission grid
6 nationally has been a bit of a patchwork quilt in
7 terms of levels of investment and how it's taken
8 the 2003 incident in the Northeast to stimulate a
9 stronger regulatory push for reliability how do
10 you see these investments in the distribution grid
11 where the outages aren't as cascading, don't
12 attract as much attention? How do you see
13 investment being stimulated there?

14 MS. CLEVELAND: That's a very good
15 question. And I think one of the problems has
16 been that in a sense there is no real financial
17 incentive. Now that we've got sort of a market-
18 driven electric utility industry there's very
19 little incentive financially to play into it.
20 That's why there has been so little investment in
21 the infrastructure, the cables, the power lines.

22 And why -- I think even though the
23 utilities every time I talk to them would
24 absolutely love to put in new technology to
25 increase reliability it comes back down to, well,

1 we can't give this to our, either the rate base or
2 to the shareholders. We just don't have the money
3 for it.

4 And again it sort of does go under the
5 radar screen a lot so that people don't realize
6 that their lack of reliability is due to the
7 distribution system.

8 ASSOCIATE MEMBER GEESMAN: I think it's
9 one of the --

10 MS. CLEVELAND: That's as good an answer
11 as I can get.

12 ASSOCIATE MEMBER GEESMAN: I think it's
13 one of the real problems we've got to wrestle with
14 here where you've got, I think, a very strong
15 technological base and I think a customer
16 community which probably has close to a critical
17 mass of customers who would like to see things
18 pushed forward but all of the inertia built into
19 our regulatory process that we need to overcome.

20 PRESIDING MEMBER PFANNENSTIEL: Thank
21 you, Frances.

22 MS. KELLY: Are there any questions from
23 the telephone? Anybody that would like to ask a
24 question?

25 Hearing none, thank you very much,

1 Frances.

2 MS. CLEVELAND: Okay, thank you.

3 MS. KELLY: Our last presenter, we do
4 have a panel but our last presenter is Mark
5 McGranahan. Mark has been working with electric
6 utilities worldwide in wide variety of technical
7 areas. He certainly travels around. Whenever we
8 here where Mark is he's in places like Greece and
9 wonderful places like that.

10 His main focus has been in the areas of
11 power quality assessments, system monitoring,
12 transient and harmonic studies and economic
13 evaluations. He is the co-author of a premier
14 book on power quality concerns, electric power
15 system quality.

16 Mark is both the national and
17 international standards development vice chairman
18 of the IEEE Power Quality Standards Coordinating
19 Committee. Mark.

20 MR. McGRANAHAN: Thanks, Linda.

21 ASSOCIATE MEMBER BYRON: Mr. McGranahan,
22 while there is a lull in the action I just thought
23 it would be worth adding that it's just great to
24 see you here. We get such high quality
25 individuals here. Usually it's Commissioner

1 Geesman that is so well-read but I'd challenge
2 him, if he has done as I have, and read your power
3 quality book.

4 (Laughter.)

5 MR. McGRANAHAN: That would be
6 impressive.

7 ASSOCIATE MEMBER BYRON: Well I have,
8 Mark. And I think it's the definitive source on
9 this so it's a pleasure to have you here today.

10 MR. McGRANAHAN: It's good to see you
11 again also, Jeff. I was going to second Jeff's
12 comment. I always enjoy coming out here. And I
13 appreciate the invitation because I think the PAC
14 that we have for this group are not only some of
15 the best experts in California for this, they're
16 some of the best experts in the world, really.

17 We did a project last year working with
18 these guys from getting a utility perspective and
19 the automation area has been tremendous. Over the
20 year we've had great success. Some of the leading
21 work that we did in power quality back in the day
22 with PG&E and others, California was the leader in
23 that work as well.

24 It's great to be here. My role now is I
25 am the director of a research area at EPRI. I am

1 in charge of the research area that includes
2 distribution systems, both overhead and
3 underground, and what we call the ADA program,
4 advanced distribution automation, which I'll
5 primarily be focusing on here. Also the power
6 quality program and our IntelliGrid program, which
7 cuts across distribution and transmission.

8 In these research programs we kind of
9 deal with the system the way it is now and making
10 it work better and trying to design the system of
11 the future using some of the concepts that Frances
12 just described.

13 Being the last speaker I could do my
14 presentation by just saying yes, I agree with
15 everything all you guys said. We've basically
16 covered it. It doesn't hurt to repeat some of
17 these things, they're important things.

18 You'll see on the second bullet there I
19 used the same number that Russ used, the same
20 number that Frances used. I can say we didn't
21 work together on this. I think we probably all
22 came up with that number independently. Russ said
23 that's the Southern California Edison number.
24 That's a number that I've got from various
25 utilities in the midwest.

1 But pretty common that around 90 percent
2 or more of customer interruptions are due to
3 distribution events. I probably shouldn't say
4 that 90 percent of the outages are due to at least
5 primarily distribution events. About half the
6 outages are due to secondary distribution, outages
7 that affect just a few customers.

8 But our reliability indices, 90 percent
9 of those indices are due to actually primary
10 distribution events, faults on a primary
11 distribution system. So there's a lot of
12 opportunity to improve reliability working on the
13 distribution system.

14 Again infrastructure. I was a little
15 bit late this morning so I missed Russ's talk but
16 looking through the slides it looked like he
17 addressed this. The fact that, you know, cables
18 are getting older, things are getting older on the
19 system. There is a good potential that it is
20 going to make reliability levels worse if we don't
21 have aggressive programs to deal with those
22 reliability impacts through replacement programs
23 that are targeted and intelligently implemented.

24 automation in terms of impact for the
25 investment is probably the best way to improve

1 traditional reliability. I think Jeff was asking
2 whether it would also improve power quality and
3 we'll talk about that in a little bit because
4 that's a little bit different question than
5 reliability. But no question in terms of what
6 regulators want utilities to improve, which is
7 usually reliability.

8 That we can do that with automation.
9 And that's one of the reasons why there's such an
10 increase in investments in automation because we
11 can do the business case for it. If the regulator
12 says, we want you to improve reliability we can
13 lay it on the table, this is how we're going to do
14 it and it's the best way to make it happen.

15 Going to the next stage of really
16 building a distribution infrastructure that can
17 integrate distributed resources and integrate
18 demand response. Some of the traditional things
19 we're doing for automating the distribution system
20 are not necessarily the same ones that will allow
21 that so that's a little bit different problem. So
22 that's kind of what we have to kind of tackle
23 next.

24 All right. As I mentioned we did a
25 project last year with Linda and Rachel and the

1 PAC in energy and environmental economics here in
2 the San Francisco area looking at the value of
3 distribution automation applications. Actually
4 distribution technologies in general. It was a
5 little broader than just distribution automation.
6 We identified some categories for where the values
7 can be realized.

8 I think it's a good summary of some of
9 the benefits that can be achieved from investing
10 in automation so that's -- We are looking at --
11 that's an active area of looking at, at the value
12 proposition. I think you heard it from the
13 Navigant work that's going on now. It's one of
14 the key things that we need to look at when we
15 look at microgrids and other things.

16 In the EPRI program in our advanced
17 distribution automation program we look at the way
18 the distribution system is today, which is
19 basically radial circuits that supply load. And
20 we see a vision, which I could throw the
21 intermediate steps up there, of a system that like
22 Frances said, has the communication and
23 information infrastructure overlaid on the
24 distribution system.

25 We have pretty much done that on

1 transmission systems. We haven't done it in a
2 completely standardized way but more standardized
3 than we have in distribution. In distribution we
4 haven't even done it. We don't have communication
5 out to devices out on the system. We don't have
6 communication to the customers to implement
7 advanced metering. It is one of the biggest
8 investments in advanced metering programs, is the
9 communication infrastructure.

10 So sensors to get more information about
11 the distribution system. Intelligent devices,
12 power electronics devices to make the system
13 operate more efficiently. Sensors to tell when
14 equipment is working and when it's not working,
15 When it's nearing the end of its life equipment
16 diagnostics is a big value proposition for these
17 sensors out on the distribution system.

18 You see a number of projects described
19 here today with looking at cable sensors. Cable
20 sensors and understanding when we need to consider
21 replacing cable or when it's likely to fail.
22 Probably one of the biggest needs that we have,
23 you know, in the aging infrastructure world right
24 now is getting a better handle on what's going on
25 out there and how close the assets are to the end

1 of their life and can we use them for longer. You
2 know, we don't want to arbitrarily replace assets
3 that are working fine so if we can get sensors
4 that help us understand that better we're going to
5 be way better off.

6 So let me just -- One of the things that
7 Linda asked me to do was just throw out some
8 information about what technologies are there now
9 as opposed to what we want to do in the future and
10 then we'll talk about what's needed. And I'll
11 start at the substation because the substation, we
12 usually have some kind of communications to the
13 substation. It's when we get out beyond that to
14 the distribution system and the customers where
15 it's less likely.

16 And we can do a lot at just the
17 substation. A lot of utilities, our SCADA
18 systems, our monitoring systems and our automation
19 systems for most utilities go to a significant
20 percentage of the substations. So if we look at
21 these breakers here in the substation a lot of
22 utilities can monitor and control those breakers
23 from a central control center.

24 And there's more advanced things that we
25 can do. A popular project that we're doing with

1 quite a few utilities now is implementing using
2 monitoring that we have at this substations anyway
3 through smart relays or power quality monitors we
4 get voltage and current wave forms that allow us
5 to calculate where the fault is out on a circuit.
6 And because we have communications we can get that
7 information back to our office fast enough, do the
8 calculation and on a map in a crew's truck tell
9 them where we think the faults are. Overheard
10 systems or underground systems.

11 This example happens to be ConEdison.
12 It's an integral part of their operations now.
13 There about 80 percent of the faults that they get
14 on their underground cables they can locate within
15 two manholes using this system. So what they do
16 is they don't even thump the cables anymore.
17 Those of you that -- what that is is to find the
18 fault they put a high voltage on it and make the
19 fault happen again and every time you do that you
20 damage the cable a little bit more. So now they
21 can get close enough to the fault that the
22 majority of the time they can find it without even
23 doing that and it saves them about an hour per
24 event in terms of repairing that cable.

25 so it's very attractive. It's Progress

1 Energy and Carolina has been using it for quite a
2 few years. There's a lot of potential to
3 implement that. That kind of technology
4 relatively inexpensive, using assets that you
5 already have. And we're probably going to be
6 working on something like this with the West
7 Virginia project where we're doing the automation
8 as part of the DOE project as well. So this is a
9 lot of potential.

10 Automation, as I said there's a lot of
11 technologies out there because the cost
12 justification to improve reliability through
13 automation is pretty clear. It's pretty easy to
14 make the business case so we're seeing more and
15 more automated switches going out on distribution
16 systems. Similar systems to what Eric described
17 in the West Virginia example that allow
18 reconfiguration of distribution systems in zones
19 and limiting the impact of an outage to the
20 smallest possible number of customers.

21 There's quite a few technologies for
22 that. DV 2010 is the research organization that
23 is implementing technologies, originally with
24 Cooper Power, now that organization is working
25 with a number of other vendors as well. SNC has

1 equipment, ABB has equipment in this area as well.
2 So there's quite a bit of equipment out there.
3 The challenge in a lot of these areas is making it
4 interoperable so we can apply it in a more generic
5 fashion rather than just applying a whole system
6 from one vendor.

7 Sensors is a big area. As we mentioned,
8 sensors for underground cable. Sensors for
9 underground cables. There's companies working on
10 optical sensors for distribution systems. This is
11 a southern company as an example of a utility that
12 has remote RTUs on most of their distribution
13 systems and do a lot of work with trying out new
14 sensors to reduce the cost of those.

15 A big cost -- When you're working on the
16 primary distribution system one of the big costs
17 in automating a system is the sensors. Sensors on
18 the low voltage systems, relatively inexpensive.
19 Sensors on the, once you get up to 13 kV the
20 sensors start to get pretty expensive and then
21 you've got to communicate to them as well.

22 We've got a project at EPRI that we've
23 been working on on cable technology itself.
24 Making the insulation, the dielectric for the
25 cable have a better voltage withstand

1 characteristic so that we can build smaller cables
2 that can handle the same power and voltage or
3 build the same size cable that can handle more
4 power. So there's a lot of potential with this.

5 Dow Chemical has just licensed that
6 technology and they're going to be building this
7 cable and we're going to be trying it out so we're
8 very excited about that, using nanofillers to
9 improve the dielectric strength of cable
10 technology.

11 I mentioned that a lot of utilities are
12 justifying automation, Hydro Quebec is a good
13 example. I like their slide so I used this one
14 when we had our international workshop at Hydro
15 Quebec last year. They have a program that has
16 been okayed by their regulator to automate
17 virtually a very high percentage of their
18 distribution systems over the next five or six
19 years. It's kind of a nice cross between research
20 work and actually putting the stuff out in the
21 field.

22 The primary driver initially is
23 reliability but over time we want to plan the
24 system so that we can also use that infrastructure
25 to integrate. They are interested in conservation

1 voltage reduction, interested in increasing
2 efficiency, integrating distributed resources and
3 so on.

4 So looking at the business drivers and
5 working backwards -- there's actually two slides
6 they use here. One is you look at the business
7 drivers. What applications do you need to
8 accomplish those business drivers and what
9 information do you need to accomplish those
10 applications. And then when you actually
11 implement it you know you go the other way.

12 International coordination. I do travel
13 around. Actually I haven't been to Greece in
14 quite a few years but I was in Indonesia recently.
15 But the international coordination is very
16 important and very active. The European
17 SmartGrids program has a tremendous amount of
18 research momentum looking at automation, new
19 control technologies for distribution systems.

20 I just did the work with Singapore a
21 little bit and Deepak Divan from Georgia Tech and
22 myself were over there and they just initiated a
23 new research initiative. They have a program
24 called the A-Star program there and they are
25 investing \$300 million Singapore dollars, which is

1 about \$170 million US dollars or so, over the next
2 five years in the Smart Grid.

3 And their objective is to make -- they
4 can see the importance of the Smart Grid
5 internationally and they want Singapore to be a
6 place that is going to supply those technologies,
7 at least for Asia if not the whole world.

8 They already have probably the most
9 reliable power system in the world, they don't
10 need a Smart Grid. The system is amazing the way
11 it works now. They don't even talk about outages,
12 they talk about voltage sags, and they try to get
13 the number of voltage sags that customers
14 experience per year down to less than one and a
15 half, which is, as Jeff probably understands, is a
16 great number. Their voltage sag numbers are our
17 outage numbers.

18 But they know that the business
19 potential of these technologies in the Smart Grid
20 area are very important and they are going to
21 spend the money to get the expertise in Singapore
22 to make that happen. So it's a very international
23 area.

24 And the coordination to accomplish
25 things that Frances was talking about, we've all

1 got to be talking the same language if we're going
2 to take advantage of technologies that are coming
3 from Singapore and China as well as technologies
4 that we develop here. And if we're going to sell
5 technologies to Singapore and China it's got to
6 be, they're all going to have to be using these
7 same protocols and languages to make that happen.

8 So we have -- Every year we conduct an
9 international workshop in the advanced
10 distribution automation area. ConEdison hosted
11 the first one two years ago and Hydro Quebec last
12 year. This year it's in Raleigh, North Carolina
13 in October and I'll just mention that.

14 This is our five areas of research that
15 we work on in the ADA program at EPRI. The
16 technologies themselves, sensors, communication
17 infrastructure, control systems aspects and then
18 putting it all together in making it work as a
19 system. So that's kind of the research areas that
20 we like to talk about.

21 So with that I'll finish up by just
22 summarizing what I think are some of the areas
23 where we do need research and it should be a
24 summary of what we've heard from virtually
25 everyone today.

1 Interoperability. There's two kinds of
2 interoperability that we talk about. There's
3 interoperability kind of at the device level when
4 we talk from device to device and being able to
5 control that device and collect the information
6 from that device. That's a set of standards that
7 fall under this banner of 61850 in IEC.

8 And then there's interoperability at the
9 systems level so that your outage management
10 system can talk to your customer information
11 system, can talk to your geographic information
12 system, can talk to your disturbance monitoring
13 system and they all can work together.

14 That fault location case that I
15 described is one of the best examples of that.
16 When we go to work with utilities to implement
17 that fault location, taking the voltage and
18 current wave forms to calculate the impedance to
19 the fault is simple. That's just, that's just a
20 simple calculation.

21 The problem then is integrating with the
22 electrical model of the distribution system to
23 figure out all the possible locations where that
24 could occur, integrating with the operations
25 database because we need to know which breaker

1 operated it to know which feeder it was on in the
2 first place. And then integrating with the outage
3 management system because that's maybe predicting
4 a section of the circuit anyway.

5 And now we're looking at the electrical
6 model we come up with five possible portions of
7 the circuit where it could be because we've got
8 all kinds of branches. But if we combine with the
9 outage management system that's probably already
10 predicting which branch it's on. So in the end if
11 we can get all these systems talking to each other
12 we can access information from all those systems
13 in a common way, we can make the thing work.

14 Right now we end up with a \$100,000
15 project with each utility to make it work because
16 we have got to figure out how to talk to that
17 outage management system and that electrical
18 model. The standards really don't exist for doing
19 that. Once we figure out how to talk to GE's
20 outage management system then we're all set and we
21 can talk to this particular model we're all set.
22 But in the distribution world there's lots of
23 different vendors and they all have their own,
24 their own systems.

25 So interoperability at the distribution

1 system level is over magnitude more difficult than
2 it was at transmission and really warrants a lot
3 of attention. I like Frances's suggestions about
4 you've got to -- you can't just write the
5 language, you've got to -- we write the language
6 and when we try it out in the field we realize we
7 forgot ten things that needed to be in the
8 language. You know, we go to access this piece of
9 data and we've got no name for it. So you've got
10 to try it out in the field and make it work.

11 The communication infrastructure itself,
12 there's a lot of potential there. I don't know if
13 we're paying enough attention to using public
14 infrastructure for that, you know. My own
15 personal opinion is that there's a lot of
16 potential there for research. Obviously there's
17 security issues and reliability issues but I think
18 there's a lot of potential to try that.

19 When we were up at Hydro Quebec last
20 year we heard from Nova Scotia. I think it was
21 Nova Scotia or New Brunswick that uses the public
22 cell phone system, GPRS, for all their
23 distribution automation. So every device that
24 they control out on the feeder circuits has a GPRS
25 receiver and transmitter on it and they don't have

1 any investment in communication infrastructure,
2 they just use the phone company.

3 But at the same time every one of the
4 phone company's cell towers is on their list of
5 priorities for restoring power just the same as
6 hospitals. So it's a sign of, it's a way that
7 they are cooperating that if there is a big outage
8 they're going to go get the -- you know, those
9 cell towers can go for a few hours with the
10 battery backup that's there. And the utility is
11 going to make every effort to get them back in
12 service as quickly as possible, which benefits all
13 the people in the area as well as their own
14 communication infrastructure. I think that kind
15 of model has potential that we should look at a
16 little bit closer.

17 Integration of technologies. I think
18 the cable, the nanotechnology in cables is a good
19 example of crossover to other industries and being
20 able to do things. Eric mentioned a project that
21 they have with Infotility and ConEdison looking at
22 the 3G system and agents.

23 And that raises a very good question
24 that I think deserves a lot, a lot of research.
25 And that is, where should the intelligence be in

1 this infrastructure where we're going to enable
2 demand response. You know, we're going to have
3 intelligence all the way down to the customers
4 thermostat. And we're going to have intelligence
5 to the substation, we're going to have intelligent
6 devices out on the distribution system.

7 What is the relative responsibility for
8 optimizing the system performance at all those
9 different levels. And that's a big question that
10 we have not figured out yet, you know. We're kind
11 of used to being a central computing industry. We
12 like, in the utility industry we like to bring all
13 the data back and solve things centrally. The
14 grid agent project is the opposite extreme. It's
15 solving everything, basically every local agent is
16 very smart and knows what to do locally with the
17 information it has while still having the
18 opportunity to optimize things at a higher level.

19 But there's a lot of potential for
20 figuring that out. Looking at what the objectives
21 of the system are going to be, the way we want it
22 to work with demand response kind of the questions
23 that we got. How do we want it to work is going
24 to help influence, you know, where we want the
25 intelligence to be. And trying out different

1 models for that makes a lot of sense.

2 And finally we heard the topic of
3 planning tools brought up as well. That's kind of
4 a pet one of mine. What we want is -- And this is
5 a big challenge. We don't have planning tools
6 that even work with automated distribution
7 systems. We don't really --

8 We plan distribution systems in our
9 traditional way to make sure that the feeders have
10 enough capacity to supply the load based on the
11 load factors and everything else. Taking into
12 account any stochastic approaches to deal with
13 automation and the fact that this feeder might
14 have to supply a portion of another feeder and
15 what's the likelihood of that.

16 As well, you know, going to the next
17 stage of demand response and the whole customer's
18 influence where probabilistic approaches are going
19 to become even more important. And those have to
20 go into the planning tools at the distribution
21 level. And then equally important, they need to
22 go into the planning tools up at the transmission
23 level. And that's also a question is how much
24 transmission do we need if we're going to have a
25 widely distributed, you know, system with lots of

1 generation all over the place.

2 But we can't even answer the question
3 unless we have planning tools that can evaluate
4 the performance of the system with those
5 distributed resources and how it affects the
6 system performance all the way up to transmission.
7 So those are some areas that I think have still a
8 lot of need to -- We haven't figured them out yet.

9 So with that I'll open it up for any
10 final questions.

11 ASSOCIATE MEMBER BYRON: Mark, I guess
12 this is a similar question to what Commissioner
13 Geesman had asked earlier. But back to your
14 business drivers. I think you had said that
15 reliability was the one that you could make the
16 best case for, the best business case for. How do
17 you make that case to, say, regulators? What is
18 the argument for the cost-effectiveness of
19 implementing? Ultimately what I'm asking you,
20 what is the argument for implementing the Smart
21 Grid here? These kinds of tools, these kinds of
22 controls.

23 MR. McGRANAHAN: I think there's been a
24 lot of studies that have been done on the cost of
25 outages, the value of fewer outages, the fewer

1 number of minutes interrupted. So you can take
2 those kinds of studies that put a value for
3 different types of customers on the outages that
4 they experience.

5 Translate that to the savings that you
6 would realize if you can improve that reliability
7 and compare that directly with the investment in
8 automation. Kind of the automation for which the
9 technology already exists now and usually it works
10 out pretty good.

11 Then there is still a question of
12 whether the regulator will -- Even though that's
13 kind of a theoretical look at the value of that,
14 that reliability. You still have to get the
15 regulator to sign off that we agree that customers
16 in our service area that we're regulating really
17 value reliability the way you're, you know, the
18 way these studies say. And if they do then they
19 usually will allow you to make those kinds of
20 investments.

21 But that automation of say automating
22 the primary feeder circuits is not the same as the
23 next level of automation, which is the whole
24 communication infrastructure for advanced metering
25 and enabling demand response.

1 The business case for that is a lot more
2 difficult because we can achieve the reliability
3 numbers without AMI. You don't AMI to achieve the
4 reliability numbers, you just need to automate the
5 feeders themselves on the primary. It's a much
6 lower investment than AMI.

7 What we need AMI for is to make the who
8 system smarter. And those benefits are they are
9 efficiency, they are optimization of the system,
10 they're equipment diagnostics using your assets
11 better. All of those, you can add them up and
12 they still don't add up unless we put something on
13 top like the demand response benefits at the
14 society level. And that's becoming less
15 controversial but even a year ago it was still
16 pretty controversial.

17 ASSOCIATE MEMBER BYRON: I'm sorry that
18 I wasn't here this morning when perhaps this was
19 discussed or addressed but are there any examples
20 in California where we have implemented a pilot or
21 a distribution system that has some of these
22 capabilities?

23 MR. McGRANAHAN: The Southern California
24 Edison system is practically all automated with
25 this kind of technology, you know, so they're

1 ready to go to the next level. They've achieved
2 the reliability benefit of this kind of automation
3 of the system that Eric described and some of the
4 technologies that I put up there.

5 You look across the country, virtually
6 every utility at least has some pilots in that
7 area or plans to look at it. It really varies,
8 the investment. Southern California is up at the,
9 you know, high end. San Diego has invested quite
10 a bit in the last two or three years would you
11 say, Tom, automating?

12 DR. BIALEK: Since mid-1995 but really
13 heavily since '99.

14 MR. McGRANAHAN: Okay. And PG&E is
15 jumping on it now in a pretty aggressive fashion
16 as well. So that's being done. It's not -- It's
17 a question of whether you want to plan that
18 automation if you haven't already done it.
19 Southern Cal and San Diego did it long enough ago
20 that, you know, they weren't talking about AMI too
21 much at the time they were doing that.

22 But now utilities like PG&E, like Duke
23 is very active in this area back in the East.
24 Since they haven't really automated beyond the
25 substation at all now they can talk about AMI and

1 distribution automation in the same sentence, you
2 know.

3 So if there are any economies in the
4 communication infrastructure to be realized they
5 can, they can look at them at the same time rather
6 than investing in a radio system for automation
7 that probably doesn't have the capacity to help
8 you much with AMI. So you have to look at your
9 AMI communication infrastructure virtually
10 completely independent. And then maybe it works
11 out economically it's best for it to be
12 independent anyway. But at least you could look
13 at the commonalities if you haven't, if you
14 haven't already gone down that path of automation.

15 ASSOCIATE MEMBER BYRON: Thank you,
16 Mark.

17 PRESIDING MEMBER PFANNENSTIEL: I may
18 jump into the question of the value of service
19 calculation. I know that's -- We have tried to do
20 that for 30 years and it has always been murky at
21 best. And it's been a number that you can kind of
22 move around at will to justify whatever you want.

23 MR. McGRANAHAN: And when we try to add
24 power quality to it it's ten times more
25 complicated.

1 PRESIDING MEMBER PFANNENSTIEL: But if
2 you take it from the other direction, back from
3 the customer perspective. Rather than what the
4 utility wants to do but rather what the customer
5 is willing to pay for or to avoid paying for, if
6 you will. If you get to a cost-based real-time
7 pricing kind of rate scheme where then the
8 customer is largely telling you how much
9 reliability he or she is willing to pay for.

10 And I know that that's probably no less
11 murky in terms of trying to decide on what those
12 exact prices are on a real time basis. But you
13 can come to some approximation of that, can't you,
14 which then gives you some sense of how much of
15 this you want to build into your system?

16 MR. McGRANAHAN: Well, having pricing
17 structures that deal with reliability, we have
18 never been very successful at. We have tried
19 things like premium power and things like that
20 have never been very good.

21 Real-time pricing is more what we talked
22 about earlier of just reflecting the actual costs
23 of generating and distributing the power and
24 translating that to, you know, the people that are
25 paying it. So making the costs more transparent.

1 Really having nothing to do with reliability, more
2 just the real-time costs of the power.

3 That has a lot of benefit in that it
4 puts the incentive to save or not save, you know,
5 matches that up better with the costs.

6 PRESIDING MEMBER PFANNENSTIEL: It does
7 seem like with AMI you have clearly incredibly
8 more information about -- you know, two-way
9 information.

10 MR. McGRANAHAN: Oh yes.

11 PRESIDING MEMBER PFANNENSTIEL: What the
12 customer is using and cost to the customer.

13 MR. McGRANAHAN: Yes.

14 PRESIDING MEMBER PFANNENSTIEL: And
15 therefore if you're building higher levels of
16 reliability into your system and you could pass
17 that through in pricing that is -- it's a more
18 sophisticated system than we currently have.
19 You're right, it doesn't give you all that
20 information.

21 MR. McGRANAHAN: Reliability
22 improvement, power quality improvement, better
23 asset management are all kind of side benefits of
24 AMI that you get. For the most part in this
25 country, other than industrial customers like

1 where Jeff used to work, they don't want to -- the
2 systems are more reliable than we're willing to
3 pay for already, you know.

4 Customers are pretty happy with the
5 reliability. They don't want to pay higher prices
6 for any reliability higher than what we have now.
7 That's at the residential level, you can correct
8 me if I'm wrong, Steve. Reliability improvement
9 does have benefits, there are benefits, but
10 customers are not willing to put a lot of -- your
11 average customers are not willing to put a lot of
12 investment into that.

13 Efficiency and helping global warming,
14 customers are much more incented right now to help
15 pay for that than they are for improved
16 reliability, I believe. And that's what has
17 changed the whole paradigm in this in terms of
18 the, you know, people looking at it. We've tried
19 to make the case for reliability, you know, year
20 after year and residential customers are just
21 pretty happy with the reliability.

22 If we can just -- And that's why
23 regulators tend to focus on things like the worst-
24 performing circuits and places on the system where
25 customers really aren't happy with the reliability

1 and getting those fixed. Around the country that
2 tends to be a focus of the regulators rather than
3 -- and not letting the reliability deteriorate.
4 Those two things more than improving the
5 reliability. So reliability benefits of AMI are
6 really, we need to think of those as a side
7 benefit but a benefit nonetheless.

8 PRESIDING MEMBER PFANNENSTIEL: Well,
9 that's AMI. But are you saying that the entire
10 distribution improvements of which we have been
11 speaking all day?

12 MR. McGRANAHAN: No, I'm not. And
13 reliability, as Russ put earlier, if we don't do
14 something about the aging infrastructure the
15 reliability is going to get worse. So automation
16 and understanding what's happening with that aging
17 infrastructure is a way to prevent that. So a lot
18 of these technologies are important just to
19 maintain the level of reliability that we have
20 today and we're going to, we'll have to do
21 something in those areas.

22 But be careful of putting too much
23 weight on the reliability number, at least in
24 terms of incremental benefits when you're already
25 very good. You know, you've got one interruption

1 per year average per customer.

2 PRESIDING MEMBER PFANNENSTIEL: Thanks.

3 MS. KELLY: Thank you, Mark.

4 That ends all our presentations. This
5 last panel, I think I want to use it to help us
6 summarize. I'll join the group. The first
7 question is I am going to ask everybody to
8 summarize and prioritize their recommendations.
9 And then the rest of the questions just should go
10 to giving us some recommendations and ideas going
11 forward.

12 ASSOCIATE MEMBER BYRON: Madam Chairman,
13 I'm going to have to excuse myself and I'm sorry I
14 couldn't be here for the whole day.

15 PRESIDING MEMBER PFANNENSTIEL: Thank
16 you for being here and congratulations.

17 ASSOCIATE MEMBER BYRON: Thanks, thank
18 you.

19 MS. KELLY: Also I want to -- I have
20 these people at the table but Steven and, Steven
21 and Eric, please, if you have a comment on any of
22 these questions if you would just come up to the
23 podium and just answer.

24 We've heard a lot of technological
25 recommendations today. The lists are long for

1 everybody. And this one, this first question here
2 asks, what are the critical technologies that will
3 enable the power delivery system to handle and
4 optimize the use of significant and concentrated
5 penetrations of renewable distributed energy,
6 storage, CHP, demand response and eventually
7 PHEVs. I note that I am not talking about
8 reliability here, I'm talking about in this type
9 of integration.

10 Could you give us one or two, your top
11 one or two so that we can get an idea of what the
12 priorities are. Maybe three. And see if that'll
13 give everybody an idea of, you know, what we'll
14 have to focus on first.

15 And then also prioritize them in time,
16 near-term technologies. Let's assume we don't
17 know where we're going yet. I think we clarified
18 that today. We know things are changing. In your
19 priorities one or two would be something we should
20 do in the near-term and what should be left to be
21 considered and evaluated for the longer term.

22 I can just start and go around.

23 Frances.

24 MS. CLEVELAND: Well, taking it from the
25 point of view of somebody who is involved in the

1 communications integration world I would say that
2 at advanced modeling of the power system, the
3 distribution power system in this case, along with
4 the communications to bring in the data that you
5 need to make the model correct, is probably the
6 most important as the basis for then moving
7 forward.

8 If you have an accurate model of the
9 distribution system including the DER, including
10 not only real-time information but also the actual
11 connectivity of the power system, the cabling, the
12 capabilities of the transformers. All of this
13 information, which I think any utility here will
14 say is probably one of the most difficult things
15 is to make that data actually accurate.

16 But if you could get it up to the level
17 where it's at least reasonably accurate then you
18 can, with this computerized model of the
19 distribution power system you can then move
20 forward and do your operations, your planning.
21 You can actually do demand response because you
22 now know and can monitor what the, what the
23 results are of any demand response action and so
24 forth.

25 So I would say that's probably my number

1 one. It's rather large because it includes a lot
2 but I'd say that's my number one focus.

3 MS. KELLY: Tom.

4 DR. BIALEK: I've got a number of them
5 here. I'll try to keep them short. But I think
6 clearly one of the things from what I have seen is
7 the issue with regards to the aging
8 infrastructure, addressing that old system,
9 rejuvenation of the system. Keeping it in a state
10 where we can actually connect things to it.

11 Absent that it is going to be awful
12 difficult to, you know, think about how are we
13 going to change things significantly when we're
14 focused strictly on the aging infrastructure
15 issues. So really a robust, physical system.

16 I would agree certainly with the better
17 analytical tools. Not just across the planning
18 perspective but tools from looking at diagnostics,
19 looking at automation, looking at decision-making
20 and how we do that, asset management in general.
21 A more extensive use of a fully automated system
22 as time goes on I think is also going to be very
23 critical to doing this.

24 And the one I think we can't really
25 forget, which is just the whole issue with regards

1 to rate design and reliability levels. Well what
2 do customers really want? What rate designs do we
3 need to give them to empower them to actually go
4 forward?

5 MS. KELLY: Thank you.

6 MR. DOW: I have two issues. I think
7 the aging infrastructure also is the first point.
8 If I had to look at what we have had to do here
9 our focus today is trying to keep the system
10 intact. And as long as we're trying to do that as
11 long as all our management energy is going into
12 that process we are not having time to look toward
13 the future. So that's the first piece.

14 And I think the second piece, if we're
15 going to -- if we are going to do this other work,
16 and we are going to do this other work, then we
17 have to be able to have interaction between the
18 customer and utility, so we have to have an open
19 protocol. So I would say those in that order.

20 MR. NEAL: This is Russ Neal. The three
21 things I always say on this is first we would
22 need, if we want to stop treating distributed
23 generation as a nuisance to go away whenever there
24 is a problem and start using it as a asset we need
25 three things.

1 The first is we need to have an idea of
2 what we want to do with it. We have to have a
3 control model. What would we like it to do so it
4 would be an asset under various contingencies.
5 Second we need a communication infrastructure to
6 make it physically possible to do those things.
7 And third, we need a win-win business model for
8 that type of integration.

9 MR. McGRANAHAN: I think I'll second
10 Frances's comment. I'd like to focus on planning
11 tools. Modeling has two parts to it and if we get
12 the models right and we can use them for planning
13 purposes then we can also then through say
14 automated means of keeping those models up to date
15 use them for real-time state estimation tools as
16 well, which we're going to need for really
17 optimizing the way we operate the system on a
18 minute by minute basis.

19 I think that communication
20 infrastructure is inherent in the second, in the
21 real-time aspects of it but the modeling aspect is
22 an important requirement right now even to get
23 going.

24 MS. KELLY: Any other comments? Eric or
25 Steven? Okay.

1 The second question here. I think we
2 have talked about automation. The critical
3 question here is, what policy and regulatory
4 changes would help provide incentives that will
5 encourage utilities and customers to invest in
6 promising technologies.

7 Again, you know, we've talked about
8 this, you know, directly and indirectly. But for
9 us to really understand what the major barriers
10 are it would be, I think really important. So if
11 you could give some suggestions about what you
12 think these changes should be or would help that
13 would be helpful. Frances.

14 MS. CLEVELAND: Well I'll pick up on
15 that with something that was discussed at GridWeek
16 a couple of weeks ago in that there is what was
17 termed a hairball of policies and regulations.

18 (Laughter.)

19 And I think that, you know, we may be
20 talking here about California but I think it's
21 impossible to move forward very cleanly towards
22 getting incentives for either both utilities and
23 customers, and vendors for that matter of
24 equipment and systems, without some movement
25 towards undoing or clarifying or pulling apart

1 this hairball of policies and regulations.

2 DR. BIALEK: I had a few here again. I
3 think from our perspective looking at more of a
4 long-term vision instead of focusing on this based
5 on a three-year rate case cycle. It would be a
6 real positive step. That is a problem for trying
7 to move a lot of these things forward because if
8 every three years you are back in front of the
9 Commission arguing as to why you need dollars to
10 invest in this it's a fundamental problem.

11 I had mentioned earlier, just things
12 like accelerated depreciation schedules for some
13 of the Smart Grid technologies allowing these
14 things to move through our systems faster.

15 And then I would also say, you know,
16 support for -- A lot of these Smart Grid
17 applications, et cetera, are at this point in time
18 really conceptual. There's a vision of what it
19 will look like, what the system will look like,
20 but we don't really know exactly how it will look
21 like. So support for R&D programs to try to flesh
22 those details out.

23 MR. DOW: In a similar vein I support
24 also, the support to acknowledge and recognize
25 that this is a risk and something is not going to

1 work. And we should not be therefore penalized
2 for things that don't work.

3 And without any details just that there
4 needs to be an incentive way, a way to incent
5 utilities to be innovative and that there is some
6 reward at the end for being innovative and not be
7 penalized for failure of a product or a project
8 that appears to have a good basis but doesn't
9 work.

10 MR. NEAL: And similarly there are two
11 things really. One is what I was crying about
12 earlier, some O&M funding for utility-based
13 research,

14 And second is when we do assume risk of
15 let's go try a circuit of the future instead of a
16 conventional circuit that entails some risk either
17 there needs to be some kind of a reward mechanism
18 or some kind of protocol that recognizes that
19 we're taking on a risk in this set of activities
20 and that we aren't going to be, you know, held to
21 the standard, how dare you take that risk type of
22 a thing. We'll be protected in some way from
23 that.

24 MR. McGRANAHAN: The UK has a regulatory
25 program, I think they call it Innovation Fund or

1 Innovation Tax, depending on how, which utility
2 you're looking at. But it basically requires that
3 utilities set aside around one and a half percent
4 of their revenues for R&D into innovative
5 technologies. And essentially they can get
6 virtually all of it back to apply their
7 technologies on their own system on things like
8 the circuit of the future and stuff.

9 For some companies like Scottish Power
10 it's worked, you know, very well in terms of
11 advancing the technologies forward. They have a
12 big problem with integrating distributed wind
13 because they have long, you know, relatively weak
14 circuits and lots of wind and everyone wants to
15 put wind farms up. But they have basically a
16 limit because of voltage regulation issues, they
17 just can't put them on distribution systems.

18 So this is -- They are developing new
19 control strategies and system voltage control
20 strategies to implement that. And it's all
21 falling under this Innovation Fund so it is one
22 example of a regulatory approach that can help
23 move the industry forward.

24 And I think just going out on a limb and
25 taking a chance, you know, like the Germans with

1 the funding for photovoltaics are good things, you
2 know. They cost money, they cost society money
3 but they move the whole technology forward.

4 Germany is the leading solar panel
5 producer in the world now. And the jobs that it's
6 produced in Germany just in terms of the
7 photovoltaics industry, you know, by some
8 estimates I have seen have exceeded the cost of
9 the whole program just in terms of the economic
10 impacts to the country. So sometimes you get side
11 benefits that you don't even think about because
12 50 cents a kilowatt hour is a lot of money to pay
13 for power but it's had a lot of other benefits.

14 ASSOCIATE MEMBER GEESMAN: Do you have a
15 sense as to what the electric utility industry
16 spends on R&D per year as a percentage of revenue?
17 This is a little bit of a trick question because I
18 know the, I know the answer.

19 MR. McGRANAHAN: I think it's in the
20 order of a half percent, isn't it? Maybe even .1
21 percent, I don't know. It's in the half percent
22 range I think. If you look at the list of
23 industries we're right down at the bottom.

24 ASSOCIATE MEMBER GEESMAN: Yes, I have
25 been told that it's at the very bottom.

1 MR. NEAL: Our rate of return is fixed
2 on the investment so we would be risking
3 investments.

4 ASSOCIATE MEMBER GEESMAN: Right, right.
5 And in California what we have done is socialize
6 that budget and transfer it over to the PIER
7 program. But I think we end up with -- well, I
8 won't go there. Thank you.

9 MS. KELLY: Well I will because the next
10 question really just was trying to start a
11 discussion about research. The one question was,
12 given the amount of research being done by the
13 manufacturing companies what research should be
14 done by public government agencies and what should
15 they focus on?

16 I think today Eric and I have given a
17 review of the research that these two
18 organizations are doing, you've given an overview
19 of what EPRI is doing and Frances has reported on
20 research that is being done, you know, in a
21 variety of sectors on interoperability.

22 So with this question the question I
23 have to ask is, have we missed anything between
24 us? I mean, it isn't necessarily what PIER should
25 do. Is there something that after you listen

1 today you say, nobody is doing this and one of
2 these organizations should pick it up. I mean
3 something that wasn't even mentioned.

4 And then the other question, maybe we
5 can just answer that separately, has to do with
6 some of the utilities now are doing a little more
7 research. Are asking for research money in their
8 rate cases. And earlier in the day there was a
9 question about the research that Luther was doing
10 and so you can answer this however -- these two
11 questions however you'd like.

12 What research should utilities be doing?
13 Or what should they consider doing, especially
14 with regard to rate cases and thinking about
15 getting back into the game again. Is it going to
16 be something that is going to grow in interest or
17 is it just some small amount of research that you
18 will ask for in rate cases and that is probably
19 all you want to do? Frances, you won't probably
20 know that but --

21 MS. CLEVELAND: Well, I am not going to
22 try to speak for utilities but I'll try and at
23 least address the previous one, which is the
24 amount of research being done by manufacturing
25 companies. Often that type of research is very

1 specific to their products and to their end game,
2 their bottom line.

3 It is, in fact, one of the reasons we
4 have so much trouble in the communications
5 information arena, is that there is very little
6 effort, and certainly very little funded effort,
7 to try to develop these cross-vendor, cross-
8 product standards. There is no money being made
9 in standards development per se so that it is very
10 difficult.

11 And we do -- What we do is we get
12 together groups of people from the vendor and
13 utilities and consultants to come up with the
14 standards but then there is almost no money at all
15 to actually test it, validate it across vendors,
16 validate across utilities and other users because
17 the vendors don't have any interest.

18 You know, maybe once we develop the
19 standard, it's there, they will implement what
20 they feel of it. But they don't try to do that
21 true interoperability. That really needs
22 additional funding from some outside source.

23 DR. BIALEK: I'm sorry, I'm just writing
24 a few down here. I think the first one, research
25 by public/government agencies, I've got a number

1 of things. As I mentioned before that the whole
2 issue with regards to reliability service levels,
3 I think that could be something that could be done
4 at a public level. Broader than just, you know,
5 the utility going out and considering its
6 customers. Because I really think that that's one
7 area that as we move forward with some of these
8 Smart Grid technologies that we're going to have
9 to really go in and answer.

10 Other ones that I put down here, things
11 with regards to rate design issues. What would,
12 what is a proper incentive mechanism, what should
13 those levels be, how do we incent customers? The
14 whole discussion with regards to cost and benefits
15 analysis. I know we have gone through several
16 sort of rule-making at the CPUC and just trying to
17 get to that with regard to technologies.

18 And then lastly, research with regards
19 to the performance of existing technologies. Are
20 we getting really what we think we're getting from
21 them. So, you know, we invest X dollars in
22 particular technologies, are really given that.

23 In particular I know this came up at the
24 PAC meeting, would we sponsor that looked at
25 performance of, for example, residential

1 photovoltaic systems. We today estimate what the
2 residential photovoltaic systems are doing by the
3 basis of what is coming out of the SGIP program
4 for larger systems.

5 And the real question is we know that
6 not everybody is going to have their PV reoriented
7 due south and providing the optimal system
8 performance. So the question really comes down
9 to, for the money that we're investing what are we
10 going to get out of it?

11 As far as from the utility perspective,
12 clearly I see for SDG&E the whole alternative
13 service model. How can we look at utilizing other
14 resources, customer-owned resources, whether it be
15 through AMI or just going directly to customers or
16 working with developers? Additionally other ideas
17 that are collaborative to advance basically the
18 industry such as, you know, the Smart Grid
19 initiatives.

20 And then lastly, you know, we have our
21 own, internal operational needs that really do
22 need R&D, do need to be funded. And they
23 certainly are public interest per se but they are
24 certainly utility interest. One could argue by
25 logical extension if they reduce rate therefore

1 it's public interest but, you know, that's one of
2 those sort of Catch-22 arguments.

3 MR. DOW: Having been an ex-EPRI
4 employee for awhile I'm a very big fan of
5 collaborative research. I think collaborative
6 research brings a lot of points of view to the
7 table and it shares, it shares the successes and
8 it shares failures. But I really support that.

9 I don't support, unfortunately, the idea
10 of trying to develop the product. So I think that
11 we set an incorrect expectation because a product
12 is a very difficult thing to -- But collaborative
13 research for knowledge and then how you use that
14 knowledge within your own company is important.

15 From a government/public agency
16 perspective, I think as Tom mentioned, these
17 issues associated with society and public benefit
18 and tariffs and all of the -- those are not
19 necessarily technical issues but they're still --
20 What is the value of service and is it different
21 from different place? Or what is the value of
22 reliability? How do you do that? Sometimes when
23 a utility does it it's seen as self-serving.

24 And what research should utilities be
25 doing? And I don't mean to be flip but I think

1 they should be doing the thing that they think is
2 important. PG&E is doing a lot of research in
3 plug-in hybrid vehicles. There's some research in
4 storage. Not doing much in the way of
5 distribution.

6 We do, the distribution research is sort
7 of very small items. We're working with NEETRAC
8 working on cable diagnostics, EPRI work on paper
9 insulated cable diagnostics. So I think it's
10 where the, it's where the major focus that that
11 utility wants to do. And I guess it's -- You
12 called it utility interest.

13 MR. NEAL: One of the topics that has
14 been coming up a little bit today is this issue of
15 quality of service and variable quality of service
16 and should somebody pay a little extra for a
17 little better service. And I think a lot of that
18 is generated from the sensitive customers who, you
19 know, they're getting a voltage dip and it's
20 causing them a process problem, where other
21 customers their lights flicker, they could care
22 less type of a thing. How should that be handled.

23 One existing means of handling stuff
24 like that is our added facilities charges. If
25 somebody wants -- we do that today, for instance,

1 if instead of having one source of feed you want
2 two sources of feed with a transfer switch. You
3 can pay a little extra for that under the added
4 facilities.

5 If we had a box that you could give the
6 customer under this added facilities charge that
7 would support his voltage during these voltage
8 upsets on the system, sort of like we talked about
9 on the Avanti a little bit there, that I had that
10 as a developed product right now, that when the
11 customers call me in and say, I'm having all this
12 problem with all your voltage dips, I could just
13 say, well then buy this little box on added
14 facilities and it will solve your problem because
15 it's all been developed.

16 Right now I don't have that available.
17 There's a few vendors that have some things but
18 they're way overpriced and not really ready for
19 prime time at this point.

20 So I would think one area that it would
21 be a little bit of R&D type of a thing that
22 somebody could do between utilities and some of
23 our joint efforts here would be to try to develop
24 some product like that that would give, that would
25 be an optional box that somebody could buy and

1 hook up on their side of the transformer and when
2 the whole system gets a ten percent voltage dip
3 they only get a five.

4 Maybe it would be an SDC, maybe it would
5 be a DVR. There's a number of technologies that
6 are promising in this but there's none of them
7 that are like off the shelf available, I can
8 guarantee this will work.

9 MR. McGRANAHAN: In general I'm in
10 agreement with Luther that it's probably not the
11 right role for EPRI or the utilities or even the
12 CEC to be developing actual products because the
13 manufacturers do that the best. And they do that
14 the best especially when, you know, they can see
15 the potential market for the product.

16 So things that affect the market for the
17 product like the incentive in Germany and things,
18 that is something that you can do. And R&D that
19 relates to the cost benefits, R&D that relates to
20 the application of the products I think is very
21 good. And we heard that a couple of times and I
22 think we need that. Manufacturers have less
23 incentive to really address all the issues with
24 applying the products.

25 Interoperability is definitely a role

1 that we have to take because the manufacturers
2 have very little incentive. They have actually
3 incentive to go the other way and make their
4 systems proprietary because then you have to buy
5 everything from them.

6 So things like the Southern California
7 Edison work in the AMI area to try to define some
8 standards that allow vendors to build the next
9 generation products in a way that they'll be
10 interoperable with each other and with the systems
11 that have to gather the data from them is still a
12 very big area.

13 Having said that I think that R&D,
14 fundamental R&D that's way out for things that we
15 haven't, the manufacturers kind of haven't thought
16 of yet, if we don't fund that at a public level
17 then a lot of times it doesn't get done. And
18 traditionally that has been a role for DOE. I
19 don't know if CEC sees themselves as a role in
20 that area.

21 That A-Star that I mentioned in
22 Singapore. You know, a lot of their research in
23 that is in that area. It has a dual purpose of
24 generating talent in the universities and the
25 country as well as doing very forward looking

1 research that might, might come up with some, you
2 know, some magic bullets down the road. But there
3 has to be outside funding for that kind of stuff
4 because manufacturers don't do it.

5 And areas like -- I think storage is
6 particularly an area that's interesting to look at
7 because there everyone knows that storage is the
8 holy grail, you know, to make the system work, to
9 make demand response work, to level the load
10 factor to make everything work together.

11 The manufacturers know it, we know it as
12 a research organization. The money that we spend
13 in the storage area as a research organization is
14 nothing compared to what the manufacturers are
15 spending. Because they know that if they come up
16 with that battery or that technology that is
17 economic in the storage area that, you know, that
18 they'll make a killing commercially.

19 So we can continue to study that, that's
20 another good example for enhancing the talent in
21 universities and stuff but we don't need to spend
22 the money. The research is going to get done, you
23 know, by the Mitsubishis of the world and what
24 have you. They are going to continue to try every
25 way they can to improve the cost benefit, you

1 know. The cost of ratios for storage.

2 MS. KELLY: Thank you. Is anybody from
3 the audience -- I didn't see any blue cards but
4 does anybody from the audience want to make a
5 comment?

6 PRESIDING MEMBER PFANNENSTIEL: Linda, I
7 actually have a couple of blue cards.

8 MS. KELLY: I'm sorry, I didn't --

9 PRESIDING MEMBER PFANNENSTIEL: And here
10 comes another one.

11 MS. KELLY: Sorry.

12 PRESIDING MEMBER PFANNENSTIEL: That's
13 okay. Richard Brent who originally was here to
14 speak on this morning's panel but then he had to
15 leave and put in a card this afternoon. But he is
16 gone. Jim Skeen.

17 MR. SKEEN: This light is green so I
18 guess it's on. I've just got two comments. One,
19 Linda's presentation this morning talked a lot
20 about a low-carbon footprint but I didn't hear any
21 numbers or any goals. I didn't get a sense of
22 whether it made a one percent difference or half
23 it, cut it in half. So I think that's a pretty
24 ill focused way to think about those programs.

25 And the other thing I'd like to say is,

1 I've lived in my house for maybe 28 years and I
2 have had one outage. And it was because I had a
3 fruit tree that eventually uprooted the service to
4 my house. So it is possible to have almost
5 perfect service.

6 And I used to be the distribution
7 engineer in the area where I live so I know why
8 it's good. The cable from the substation out has
9 never been overloaded. It's had fast relays. It
10 has never been subjected to a lot of I-square-T
11 and there's a lot of overhead line.

12 And the trouble man that I used to work
13 with have passed on to the new trouble men that
14 are doing the work now. The trees along the route
15 to my house are trimmed and all the fuses are
16 appropriately sized. So that's just attention to
17 detail.

18 And I guess what worries me about the
19 discussion, I'm interested in all this new
20 technology and I have had a lot of fun with it
21 over the years, but you haven't -- by the time you
22 address replacing all the poles that Luther listed
23 that are over 40 years old you won't have much
24 money left over, will you?

25 PRESIDING MEMBER PFANNENSTIEL: Thank

1 you, sir. And Charles Toca on the phone.

2 MS. KELLY: Can I just make one comment?

3 PRESIDING MEMBER PFANNENSTIEL: Of
4 course.

5 MS. KELLY: Yes. With regard to
6 quantifying. I think that it's very interesting
7 you mentioned that because I am just working on
8 developing metrics to help us quantify the value
9 of a low-carbon network. It won't be easy. We
10 know a lot of the values are hard to quantify.

11 As you've indicated, what is the value
12 of PV. But I think that we're -- we think that it
13 is an appropriate objective and vision and we are
14 in the process of developing metrics to help us
15 understand what the value of this will be and what
16 the costs will be as well.

17 PRESIDING MEMBER PFANNENSTIEL: Thank
18 you. On the phone, Mr. Toca.

19 MR. TOCA: Hi, this is Charles Toca.
20 I'm a (indiscernible) for VRB Power System, which
21 makes a large flow battery, utility size of ten
22 megawatts. I was interested in the comments on
23 energy storage and I appreciate, I think it was
24 Mark's comments, on storage being the holy grail.

25 But I wanted to speak to Russ Neal's

1 comment and ask a question along those lines. We
2 were talking about, how can storage and some of
3 these technologies be integrated. Russ mentioned
4 earlier, I think it was him, that he said that
5 every time the utility pencils out distributed
6 generation for distribution that it didn't make
7 sense, it didn't work out economically. But Russ
8 also mentioned plug-in hybrids and that sort of
9 thing might work economically because they help to
10 utilize under-utilized generation right now.

11 I was wondering if he could speak to if
12 there are plans by any of the utilities to look at
13 large energy storage in place of or as a DG plug-
14 in for distribution and to include those kinds of
15 economics into the process to see if it does make
16 sense in that case for a distribution application.

17 MR. NEAL: Well yes, this is Russ.

18 We're very interested in that. It's
19 always been, like we said, obvious that if you had
20 a substantial, economic, reliable energy storage
21 thing that you could do load leveling on your
22 system there would be a lot of better capital
23 utilization going on and that sort of thing.
24 We're interested in that. We have not seen a
25 proposed energy storage system at the distribution

1 circuit level that was attractive at this point.

2 DR. BIALEK: This is Tom Bialek. One of
3 the other things, in particular one of the things
4 we've seen, is that in the applications where we
5 have actually used distributed generation on our
6 system to support substations and/or carry
7 customers the things that we found, the particular
8 applications were at some remote locations where
9 we ran diesel generators. And clearly given sort
10 of where diesel is going it becomes problematic.

11 And certainly from -- And there is no
12 natural gas in those areas either so you sort of
13 have a little bit of a problem. But energy
14 storage, storage batteries, flow batteries,
15 whatever, some of those kinds of technologies
16 really have to become a little bit more attractive
17 in those areas.

18 Because if you can get them in there and
19 the cost is reasonable then we can do the same, we
20 expect we'll be able to do the same thing as we do
21 with DG. But at this point in time, again just
22 like Russ said, we haven't found an application
23 where it has been cost-effective.

24 MR. NEAL: If I could just give an
25 example. We've got Catalina Island 30 miles off

1 the coast. It's got three megawatts of load,
2 something less than half of a circuit. And we're
3 considering running a 33 kV cable all the way out
4 there instead of using the distributed generation
5 out there as a better choice. So it kind of gives
6 you an idea of where it pencils out.

7 PRESIDING MEMBER PFANNENSTIEL: Thank
8 you. Is there anybody else here who would like to
9 make comments? Anybody else on the phone?

10 Yes, please come up to the podium.

11 MR. SCHWARTZ: Thank you, Commissioners,
12 I'm Peter Schwartz. I just wanted to make a quick
13 comment. We had discussions of R&D funding and
14 how can we stimulate that and what are some of the
15 drivers for that. And some of the comments that
16 were mentioned earlier had to do with the creation
17 of markets either through sort of smart rates and
18 tariffs.

19 And I think those types of incentives
20 can go a long way to just stimulating private
21 industry to do R&D. We have heard that
22 manufacturers do R&D pretty well themselves. So
23 if you help create the environment and do it over
24 a life cycle or a time frame that is long enough
25 for the investment the market will tend to move

1 rather quickly. In many cases much more quickly
2 than the CPUC can move. So I just wanted to make
3 that comment, thank you.

4 PRESIDING MEMBER PFANNENSTIEL: Thank
5 you. Others?

6 Is there any questions on the telephone?
7 Questions on the telephone? No.

8 A fulsome day. Commissioner Geesman,
9 any concluding comments?

10 ASSOCIATE MEMBER GEESMAN: I thought it
11 was an outstanding workshop. I want to compliment
12 all of you for your input to us today and I can
13 assure you that it will be well received. We'll
14 go over various written materials, review the
15 transcript and I think give it a lot of thought in
16 drafting the report that ultimately will come out
17 this fall. I again want to thank you very much.

18 PRESIDING MEMBER PFANNENSTIEL: And I'll
19 add my thanks to those. If there is any problem
20 with today's workshop it was that it was almost
21 too meaty. There's a lot going on in this field
22 and we need to be able to digest it and apply it
23 to some of the many problems and issues that we
24 face.

25 But clearly we have a deep record, both

1 technical and I think a lot of policy guidance
2 here so thank you all. I thank the staff. I
3 think you did a great job in pulling this together
4 so thank you very much.

5 MS. KELLY: Could I just say one thing?
6 If anybody has written comments that they would
7 like to provide after this workshop if you could
8 provide them to me within, not this week but
9 obviously by the end of next week we'd be glad to
10 see them. Thank you very much.

11 PRESIDING MEMBER PFANNENSTIEL: All
12 right, we'll be adjourned.

13 (Whereupon, at 4:33 p.m., the Committee
14 workshop was adjourned.)
